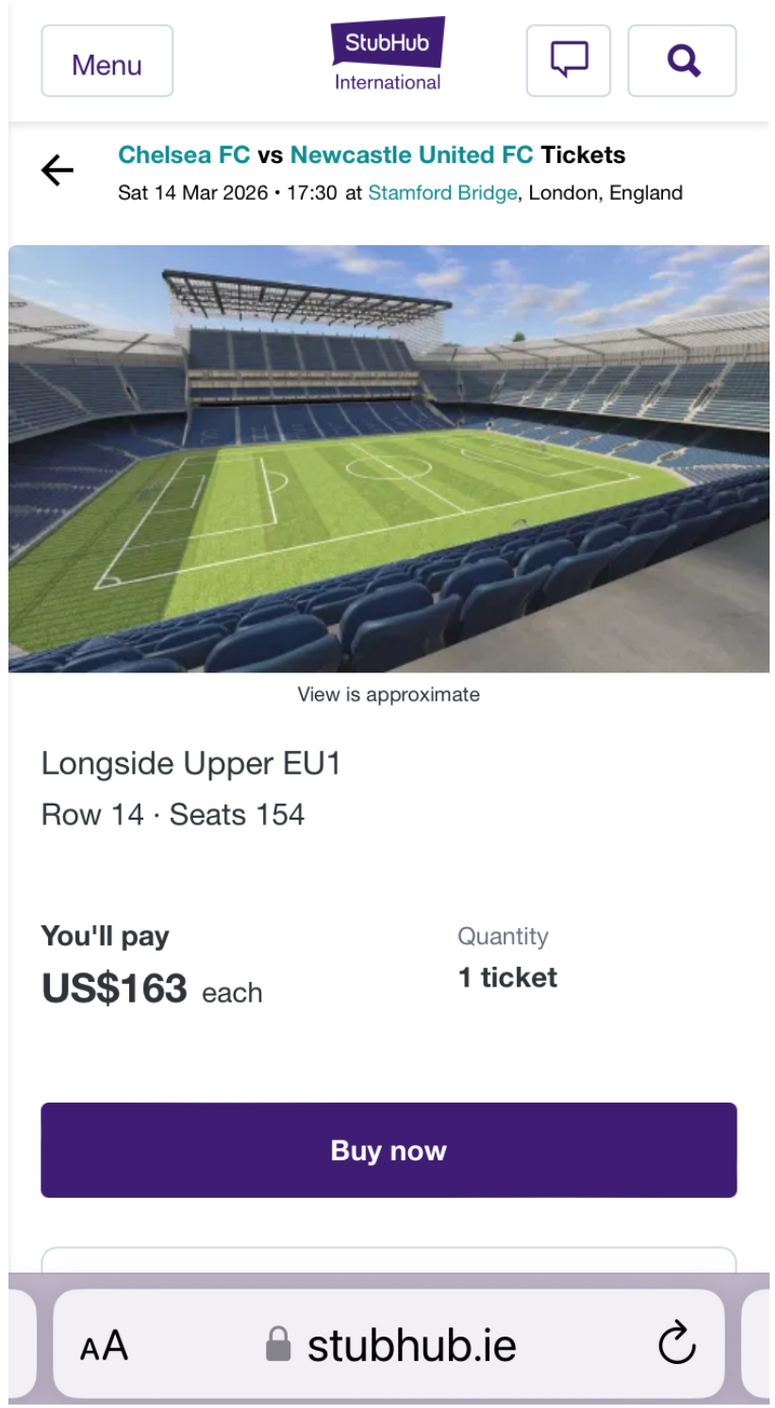
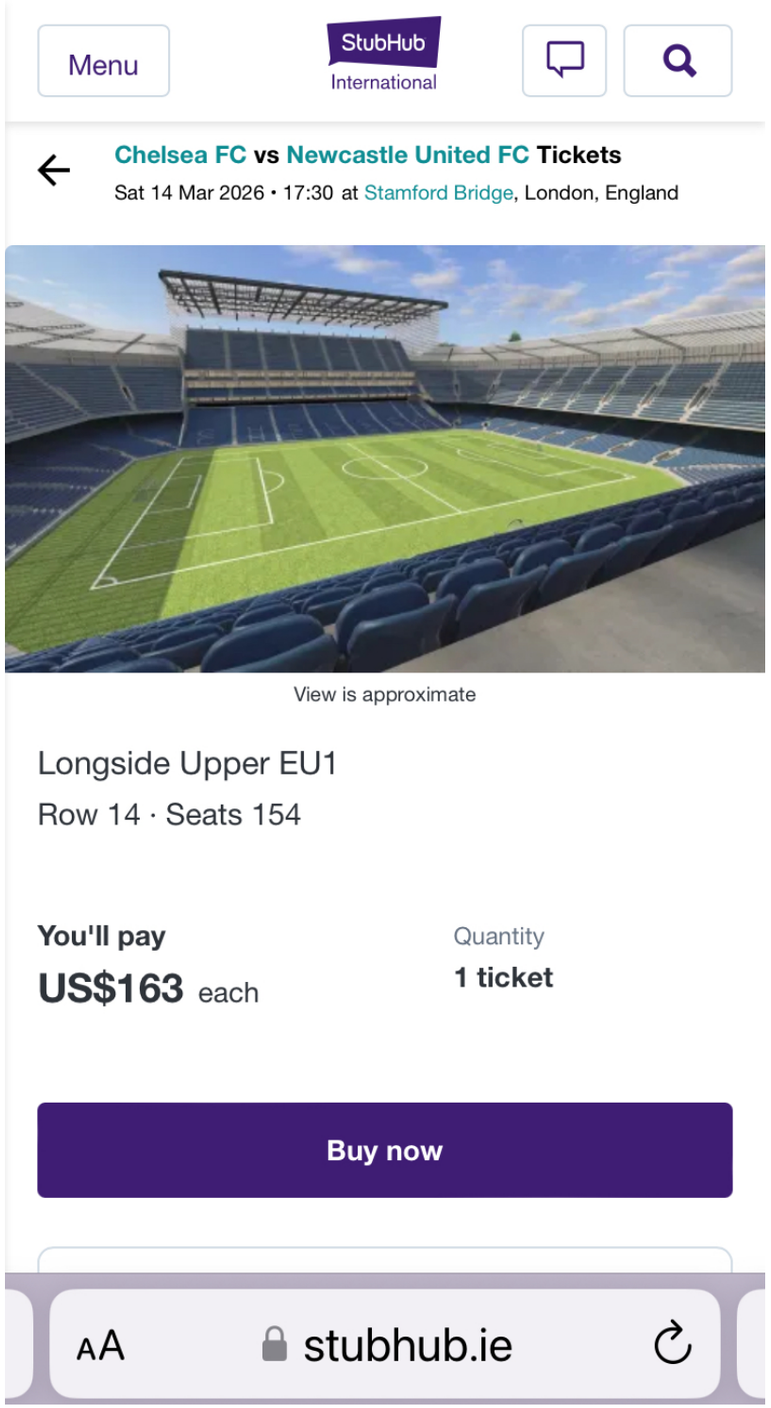
An example of hidden fee

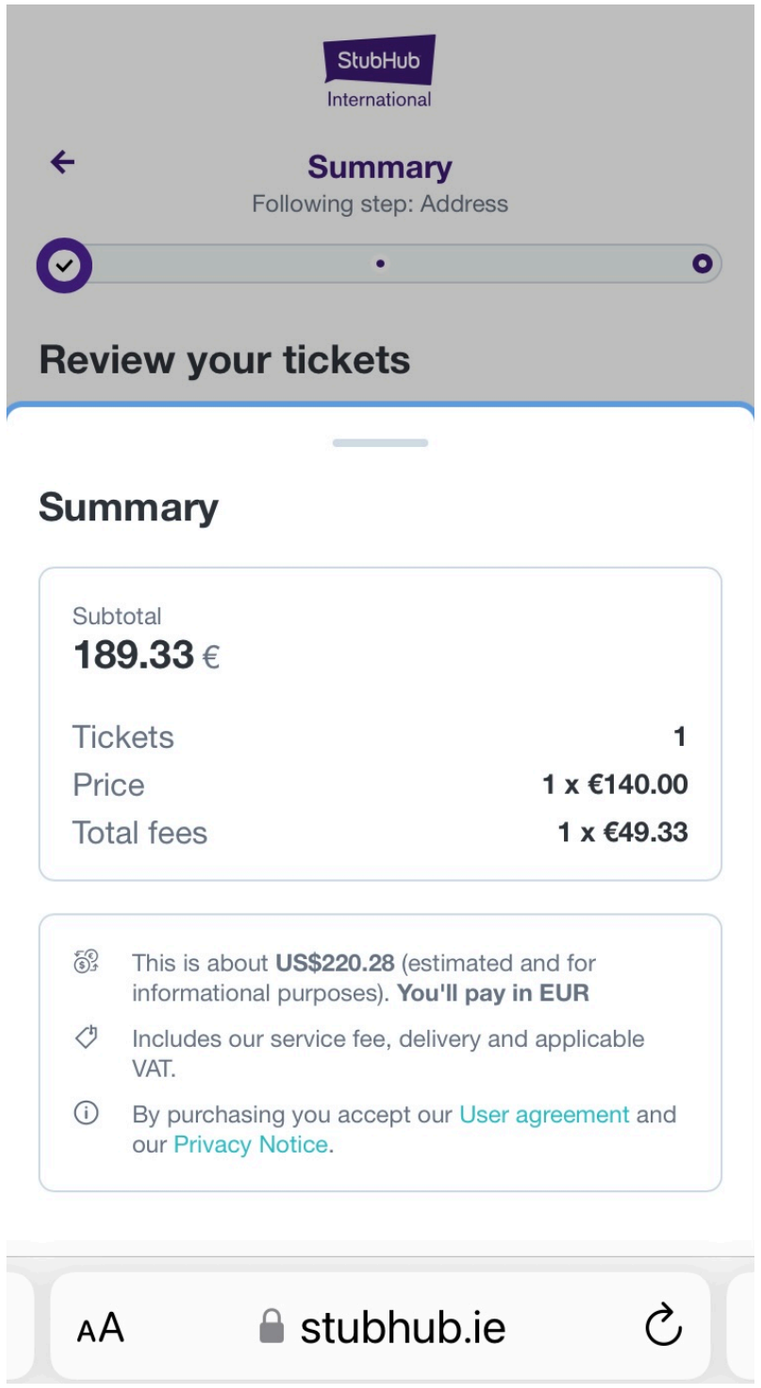
StubHub:



An example of hidden fee

StubHub:





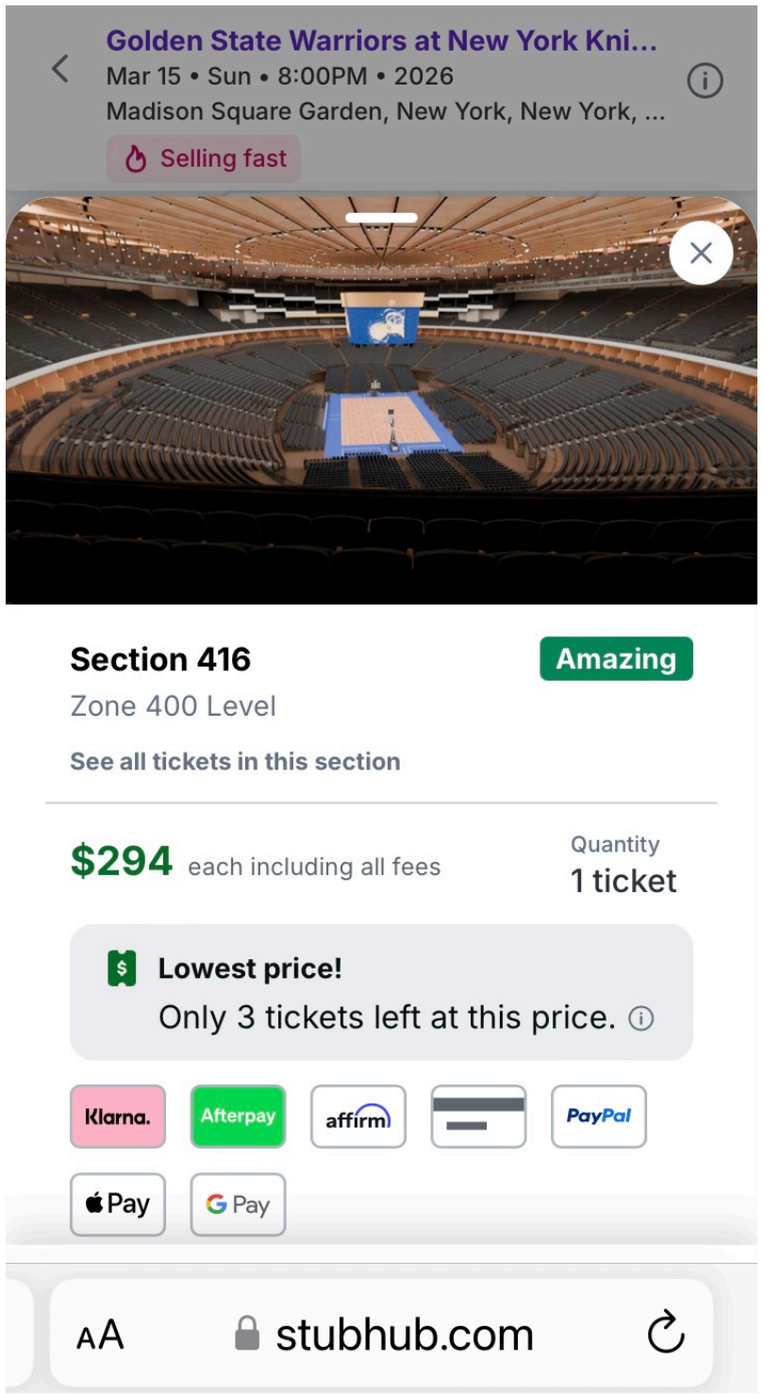
Hidden fee is impactful

- Blake et. al (2021): hidden fee leads to
  - **21%** more money spent
  - **14%** higher purchase likelihood
- Many other studies find that hidden fees affect demand
  - Chetty, Looney, and Kroft, 2009; Brown, Hossain, and Morgan, 2010; Feldman and Ruffle, 2015; Feldman, Goldin, and Homonoff, 2018; Bradley and Feldman, 2020

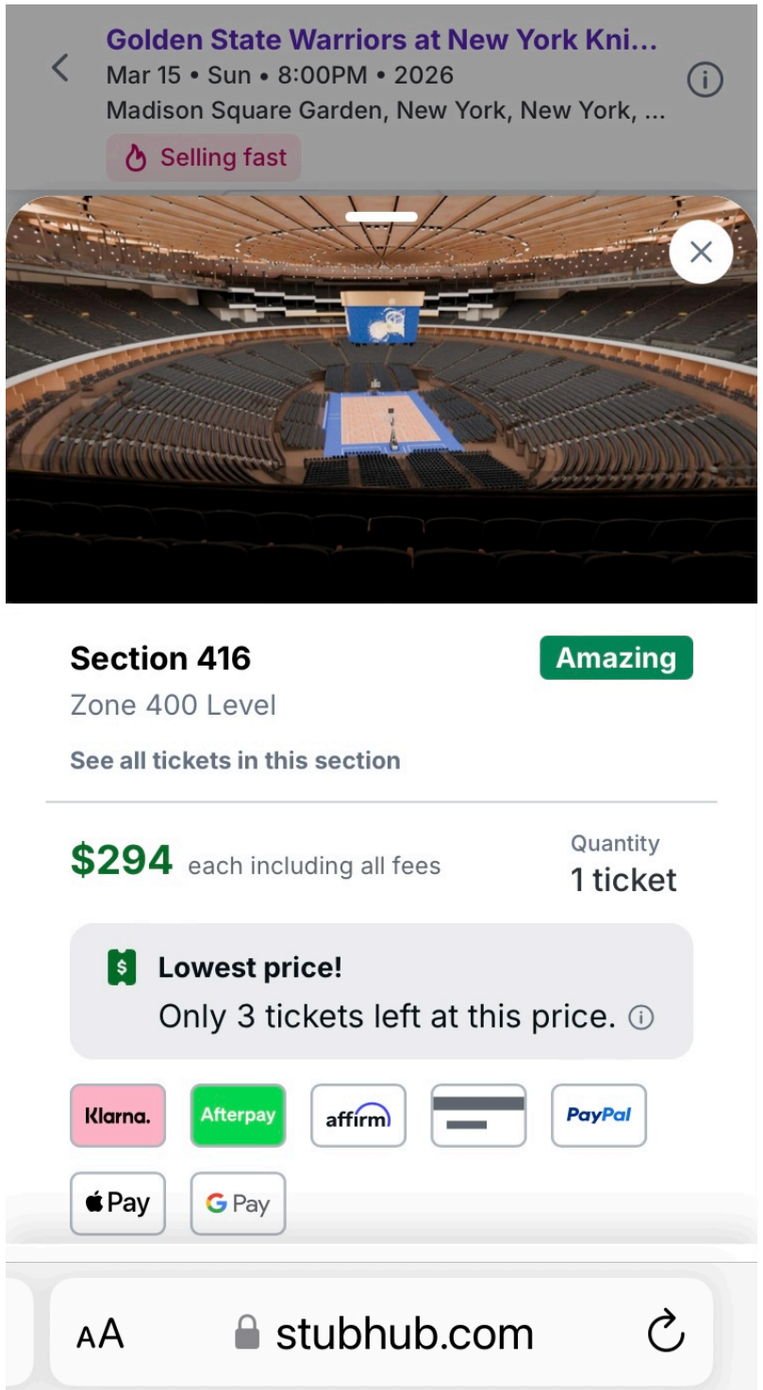
Regulations

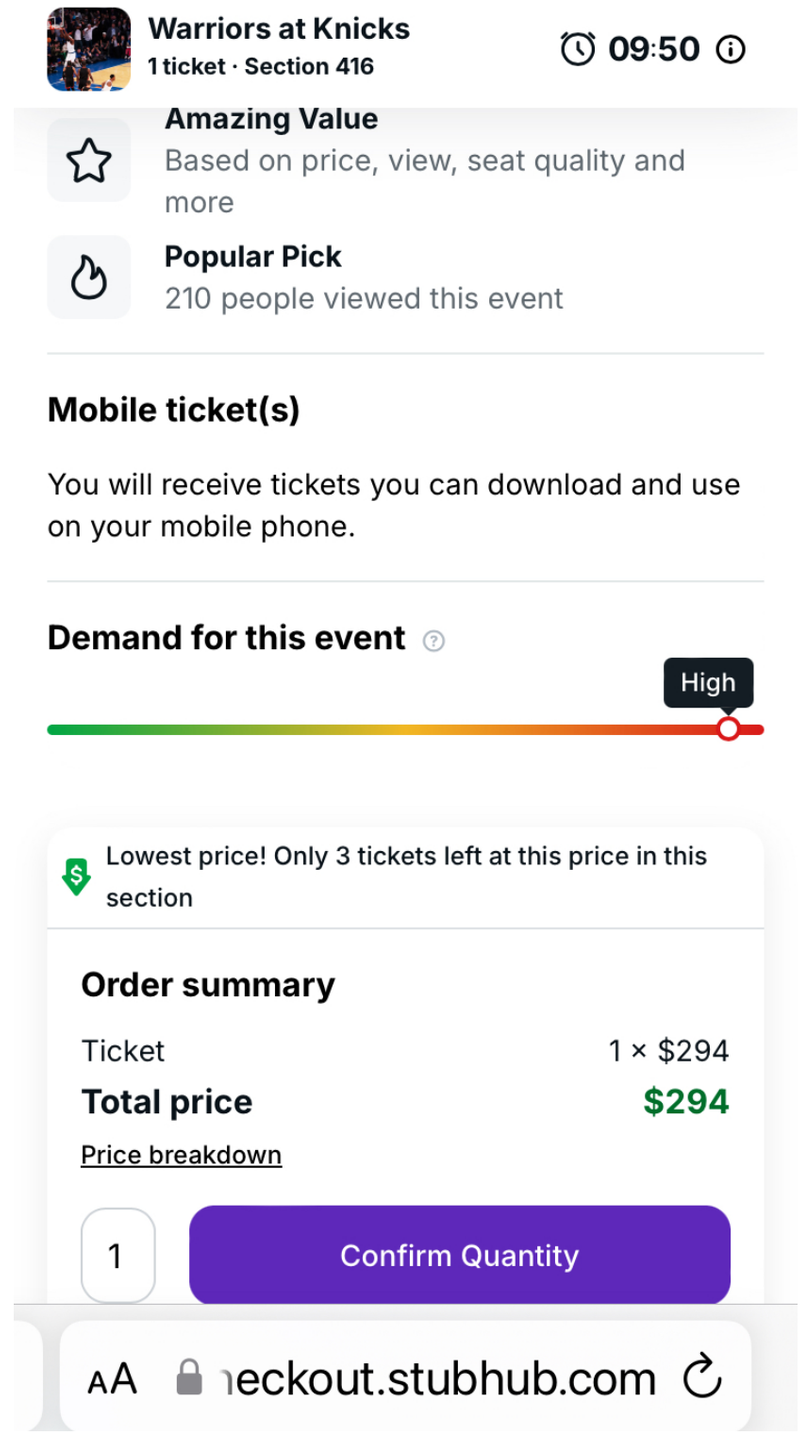
- **New York (2022):** "all-in pricing" law for live event tickets
- **California (2024):** "Hidden Fees Statute" (SB 478) for most consumer transactions
- **Federal Trade Commission (2025):** "Junk Fees Rule” for live-event tickets and short-term lodging
- **European Union (Payment Services Regulation):** In negotiation for international payments

Regulations



Regulations





Existing explanations for hidden fees

- Blake et al. (2021):

``[Consumers] may believe that they have found a cheap enough ticket to warrant purchase, and proceed to the checkout page … Upon reaching the checkout and purchase page, the ticket's actual price - including all fees - is revealed. ***Absent behavioral biases****, the consumer ought to exit without buying the ticket, but we assume that some consumers will complete their purchase due to* ***loss aversion or other behavioral biases****."*

Existing explanations for hidden fees

- Consumers are temporarily unaware of the existence of hidden fees initially

  Empirical support: Jin, Luca, and Martin, 2021; Montero and Sheth, 2021; Brown, Hossain, and Morgan, 2010; Brown, Camerer, and Lovallo, 2012; Sheth, 2021; Sah and Read, 2020

- Once hidden fees are revealed at checkout, some kind of **behavioral bias** (e.g., sunk cost fallacy, salience, loss aversion) leads to the final conversion

  Koszegi and Rabin, 2006, Chetty, Looney, and Kroft, 2009; Goldin and Homonoff, 2013

This paper

- Provides an explanation for why hidden fees benefit the firm by considering **consumer search**

- Examines the policy implications of the (dis)use of hidden fees.

This paper

- Provides an explanation for why hidden fees benefit the firm by considering **consumer search**
  - Hidden fees can create a market from scratch
  - Hidden fees can make consumers more resilient to bad news
- Examines the policy implications of the (dis)use of hidden fees.
  - Hidden fees always reduce social welfare when customer base is homogeneous
  - Hidden fees may increase social welfare when consumers are heterogeneous

Related Research

- Shrouding can persist in equilibrium under consumer unawareness: Ellison 2005, Gabaix and Laibson 2006

- How consumer unawareness shapes equilibrium pricing in markets with **add-ons**: Gabaix and Laibson 2006; Armstrong and Vickers, 2012; Johnen and Somogyi, 2024; Heidhues, Koszegi, and Murooka, 2016; Kosfeld and Schuwer, 2017; Shulman and Geng, 2013; Geng, Tan, and Wei, 2018; Erat and Bhaskaran, 2012

Related Research

- **Optional add-ons**: remain unnoticed when the base product is purchased
  - Standard shrouded-attributes mechanism: consumers purchasing the base product without fully accounting for add-on prices
- **Mandatory fees:** disclosed before the transaction is finalized
  - Hard to reconcile with the standard shrouded-attributes logic

Basic consumer search model
(Branco, Sun, Villas-Boas 2012 MS)

- A firm offers a product with a marginal cost of m and price p
- A consumer decides whether to buy it
- The consumer can search for information before making a decision

  initial valuation: v_0 (common knowledge)

  search cost: c per period of time

Basic consumer search model
(Branco, Sun, Villas-Boas 2012 MS)

- The consumer gradually learns about various product attributes to update her belief about the product's total value

- Each attribute i has a value of $x_i = \pm z$. The product's total value based on the t searched attributes is $v_0 + \sum_{i=1}^{t} x_i$.

- Infinitely many attributes & each with a very small weight:

$\Rightarrow$ consumer's valuation becomes a Brownian motion:

$$dv_t = \sigma dW_t \, (z = \sigma\sqrt{dt})$$

Basic consumer search model
(Branco, Sun, Villas-Boas 2012 MS)

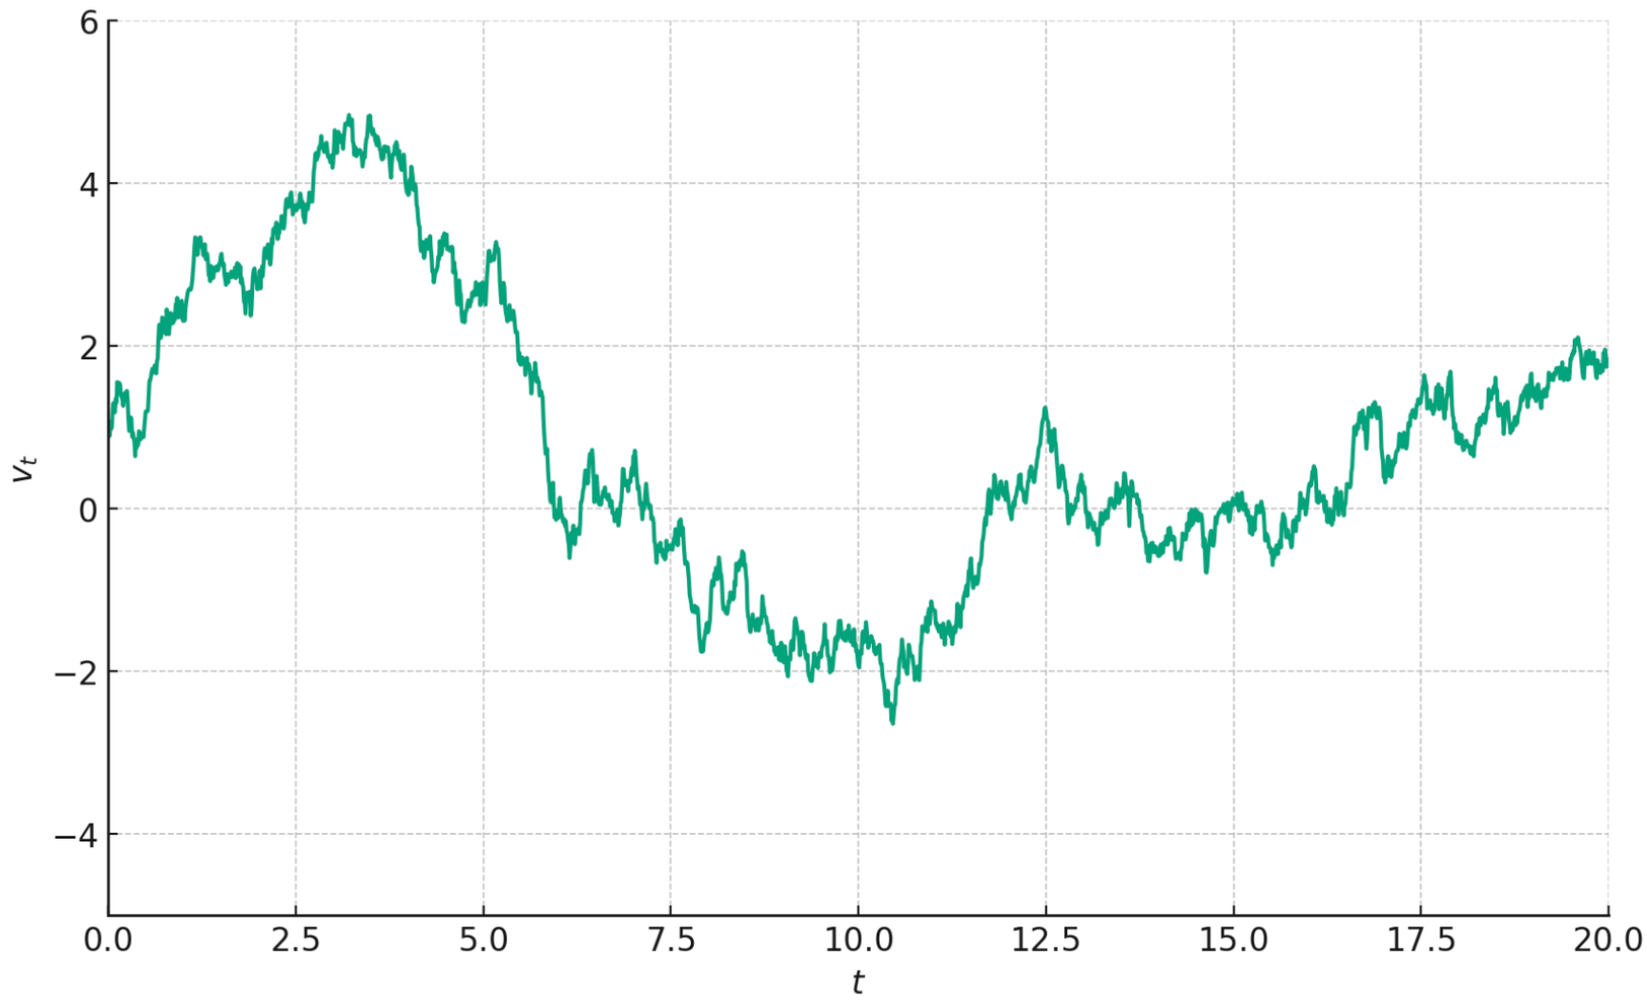
- True value of the product π_t is changing over time
  $d\pi_t = \sigma dW_t^{\pi}$, where $\pi_0 \sim \mathcal{N}(v_0, \sigma\sigma_S)$

- Consumers learn about $v_t = \mathbb{E}[\pi_t]$ by observing the signal
  $dS_t := \pi_t dt + \sigma_S dW_t$

- $dv_t = \frac{\sigma}{\sigma_S}(\pi_t - v_t)dt + \sigma dW_t$, or, by Levy characterization,

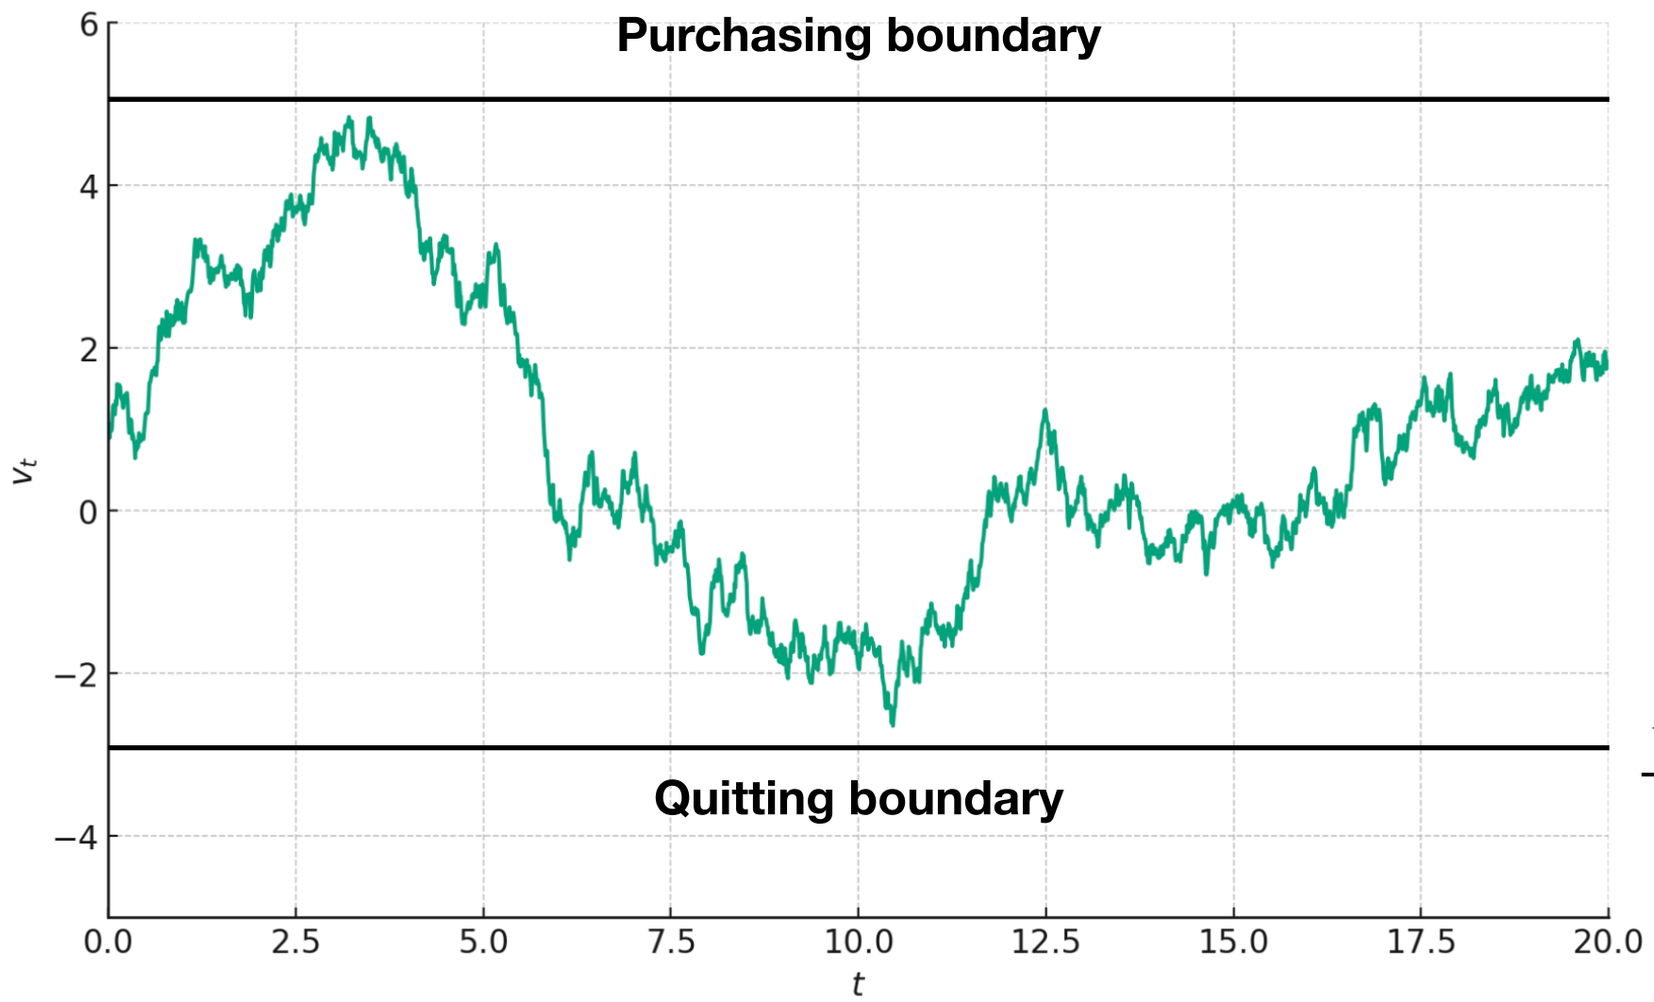
  $dv_t = \sigma dW_t^{v}$

Sample path of the consumer's learning processes



$$v_0 = 1$$

Consumer's search strategy

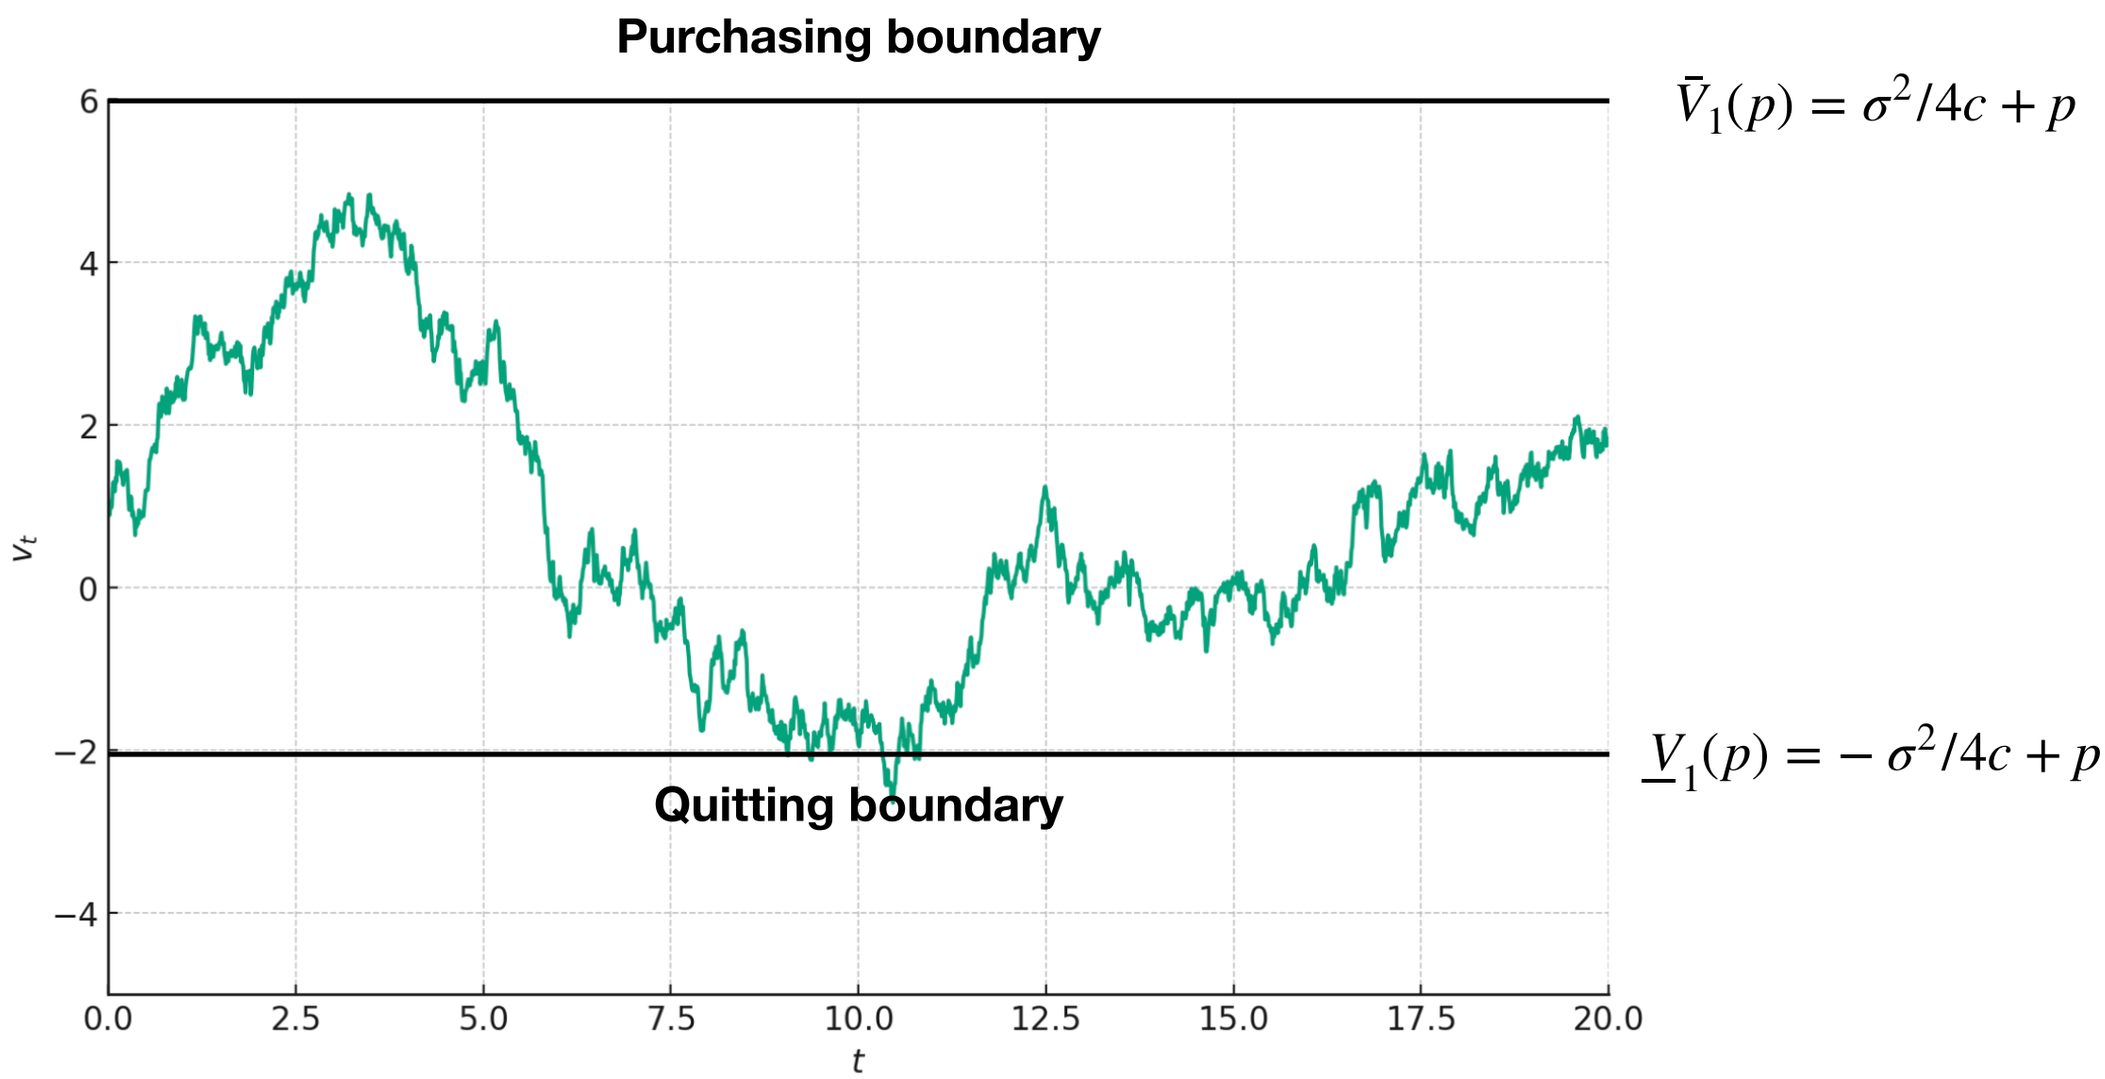


$\bar{V}_1(p) = \sigma^2/4c + p$

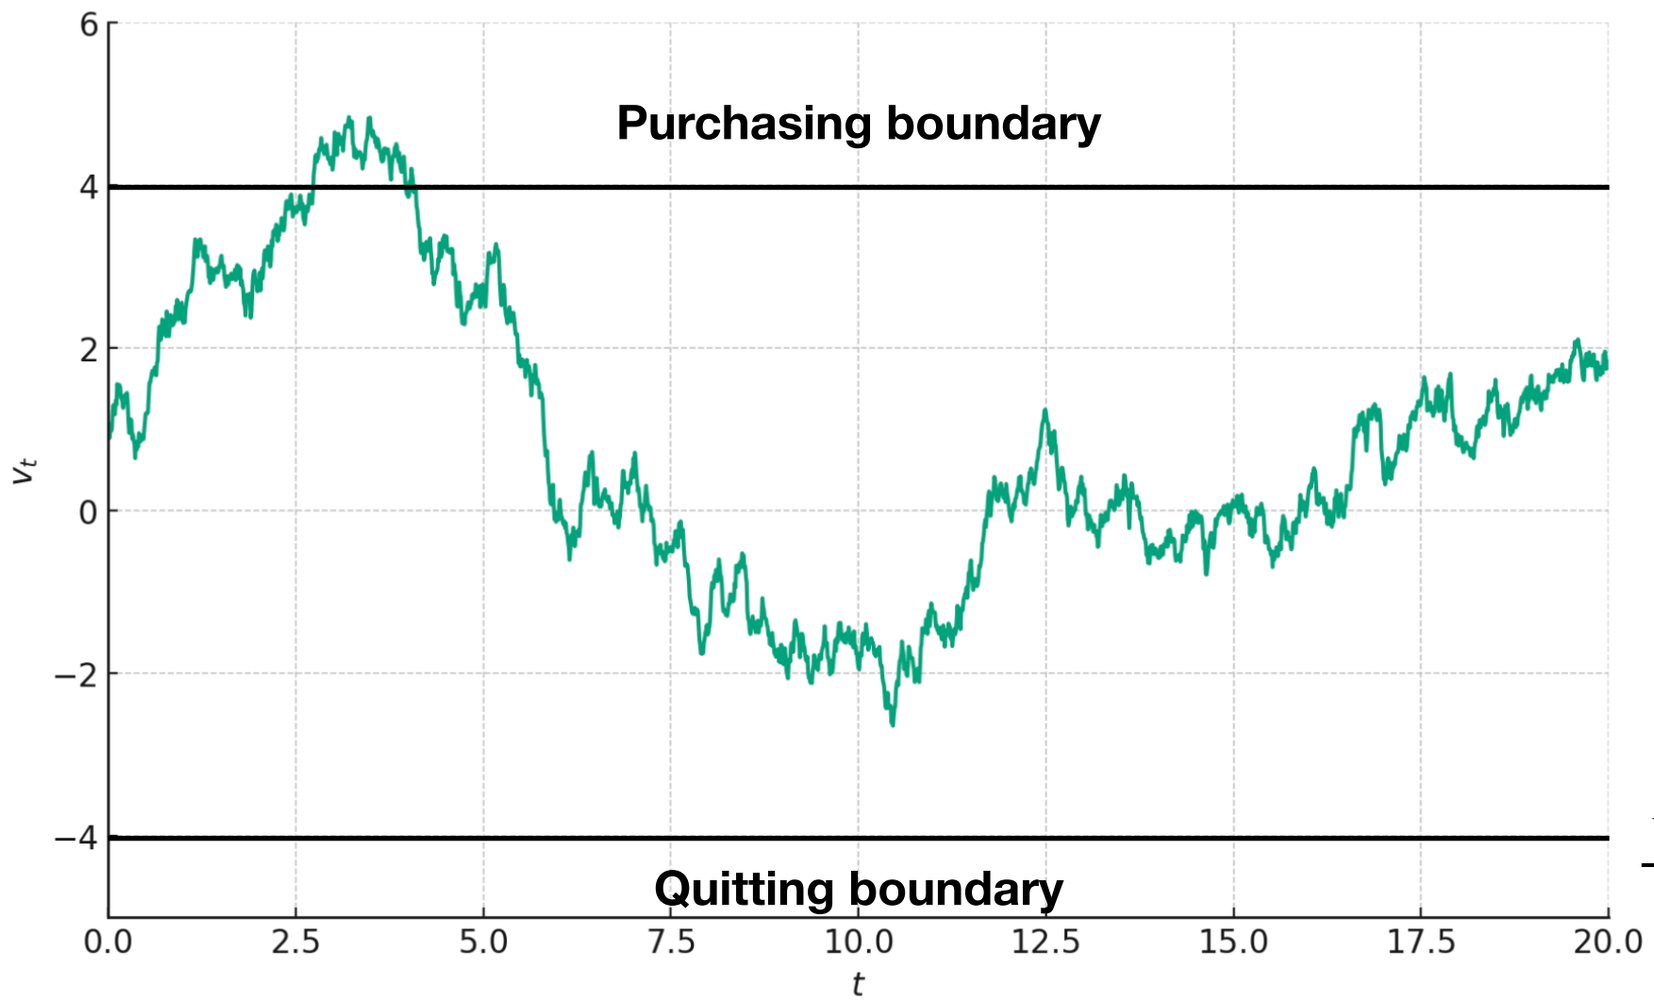
$\underline{V}_1(p) = -\sigma^2/4c + p$

$v_0 = 1,\ p = 1,\ c = 0.01,\ \sigma = 0.4$

Higher price shifts the thresholds upwards linearly



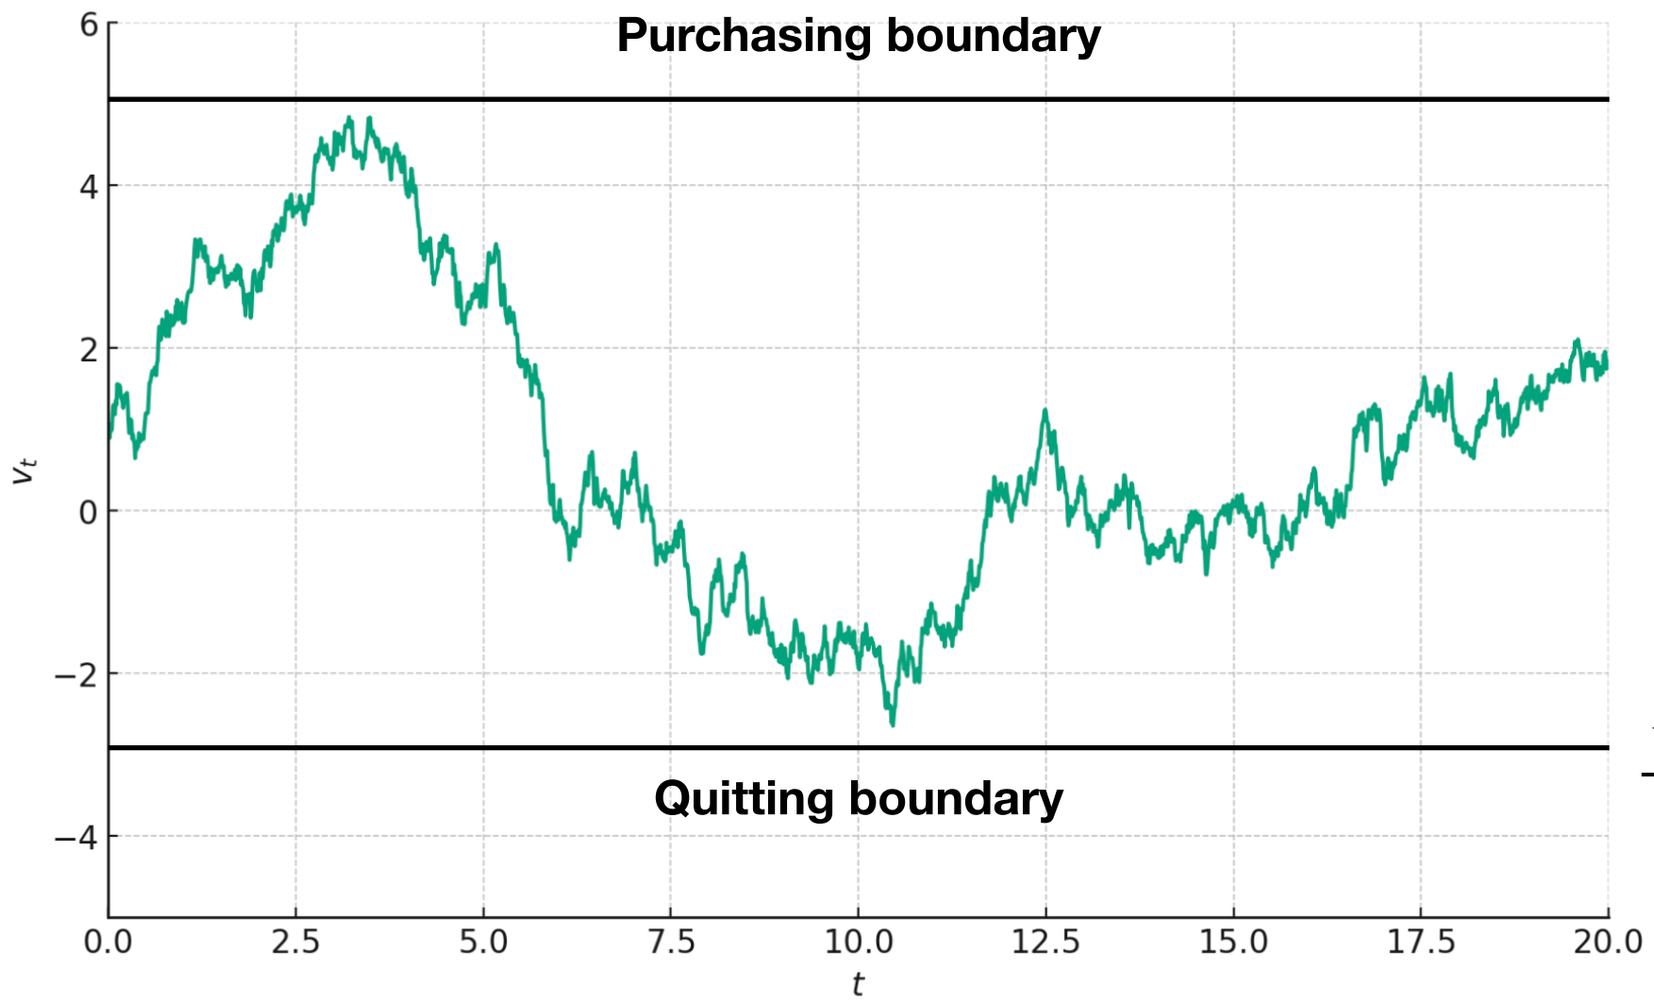
Lower price shifts the thresholds downwards linearly



$\bar{V}_1(p) = \sigma^2/4c + p$

$\underline{V}_1(p) = -\sigma^2/4c + p$

Consumer's search strategy

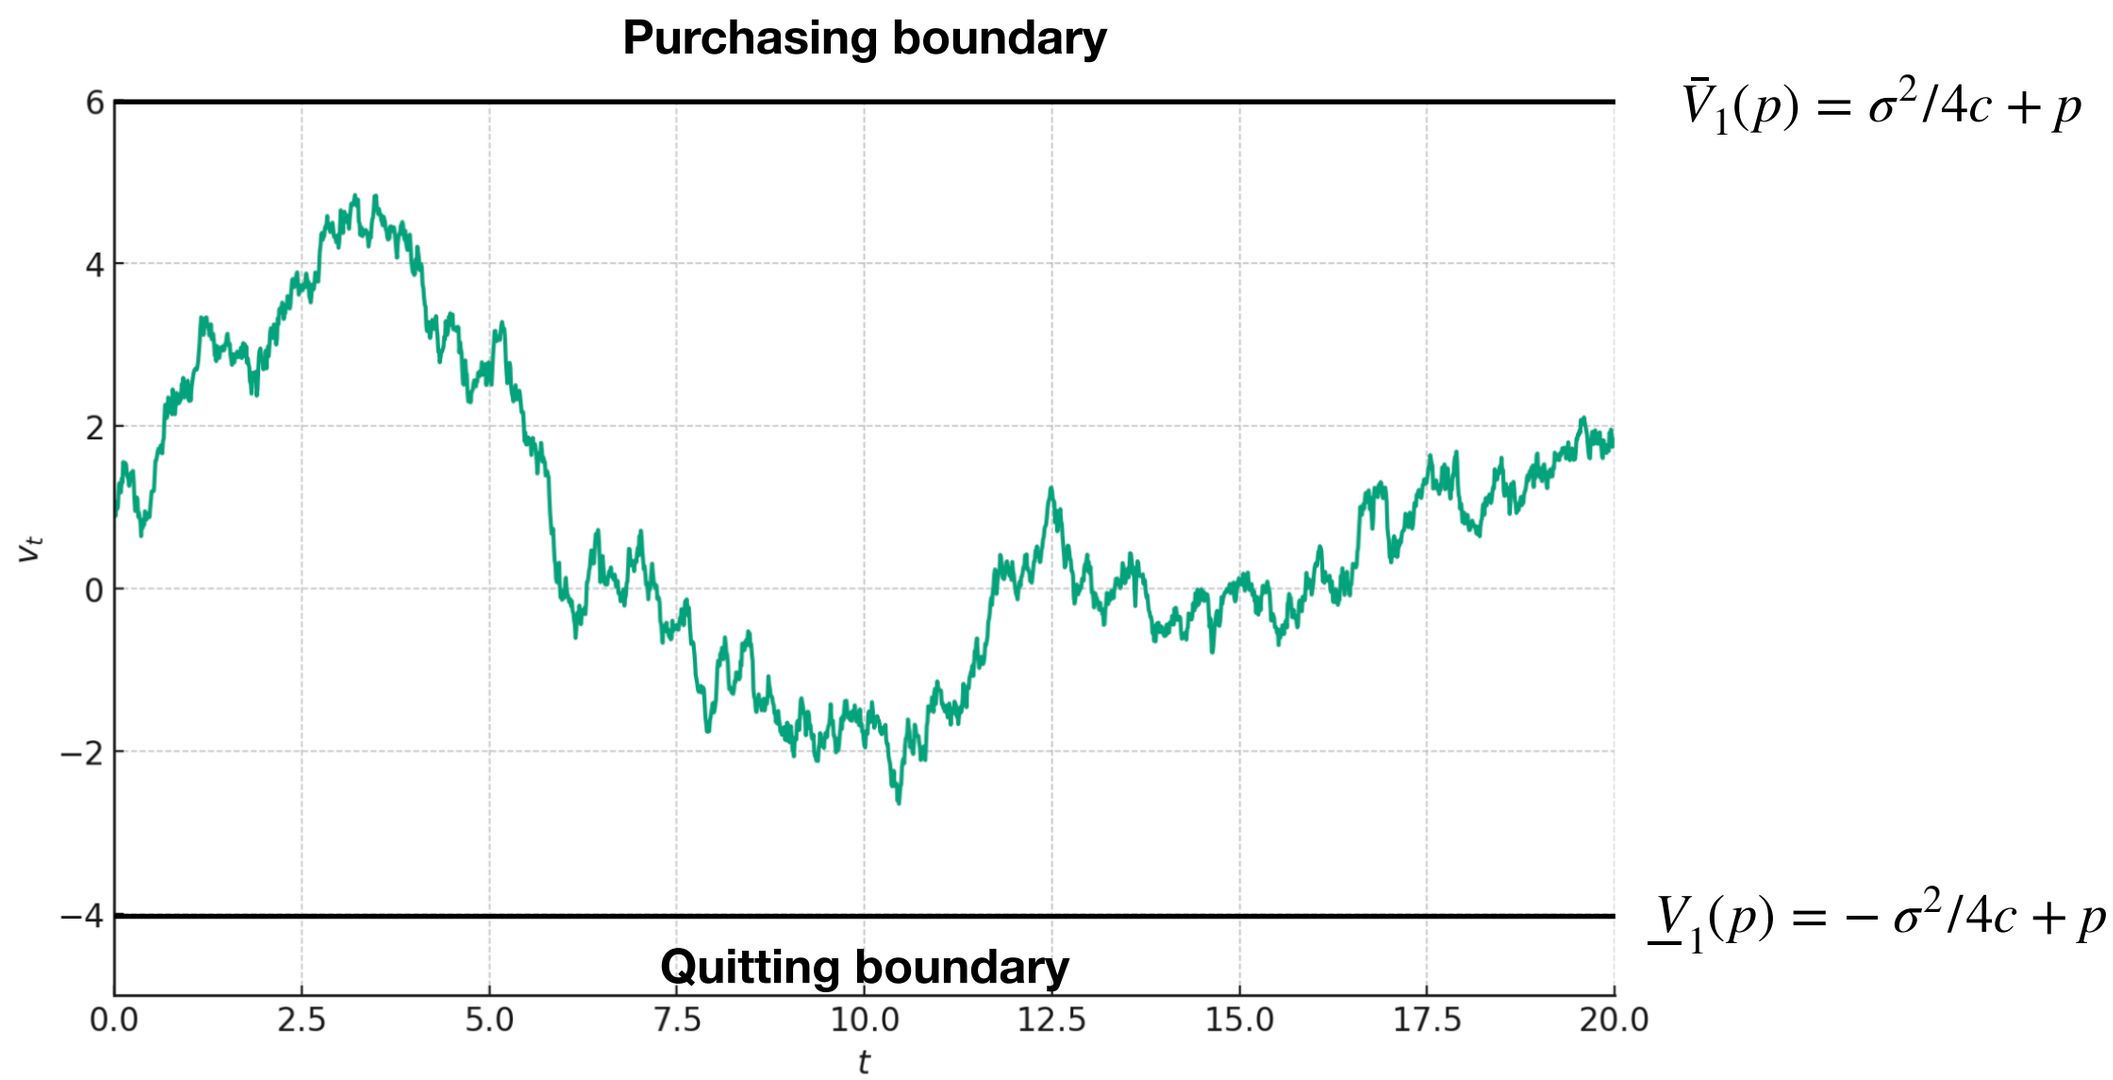


$\bar{V}_1(p) = \sigma^2/4c + p$

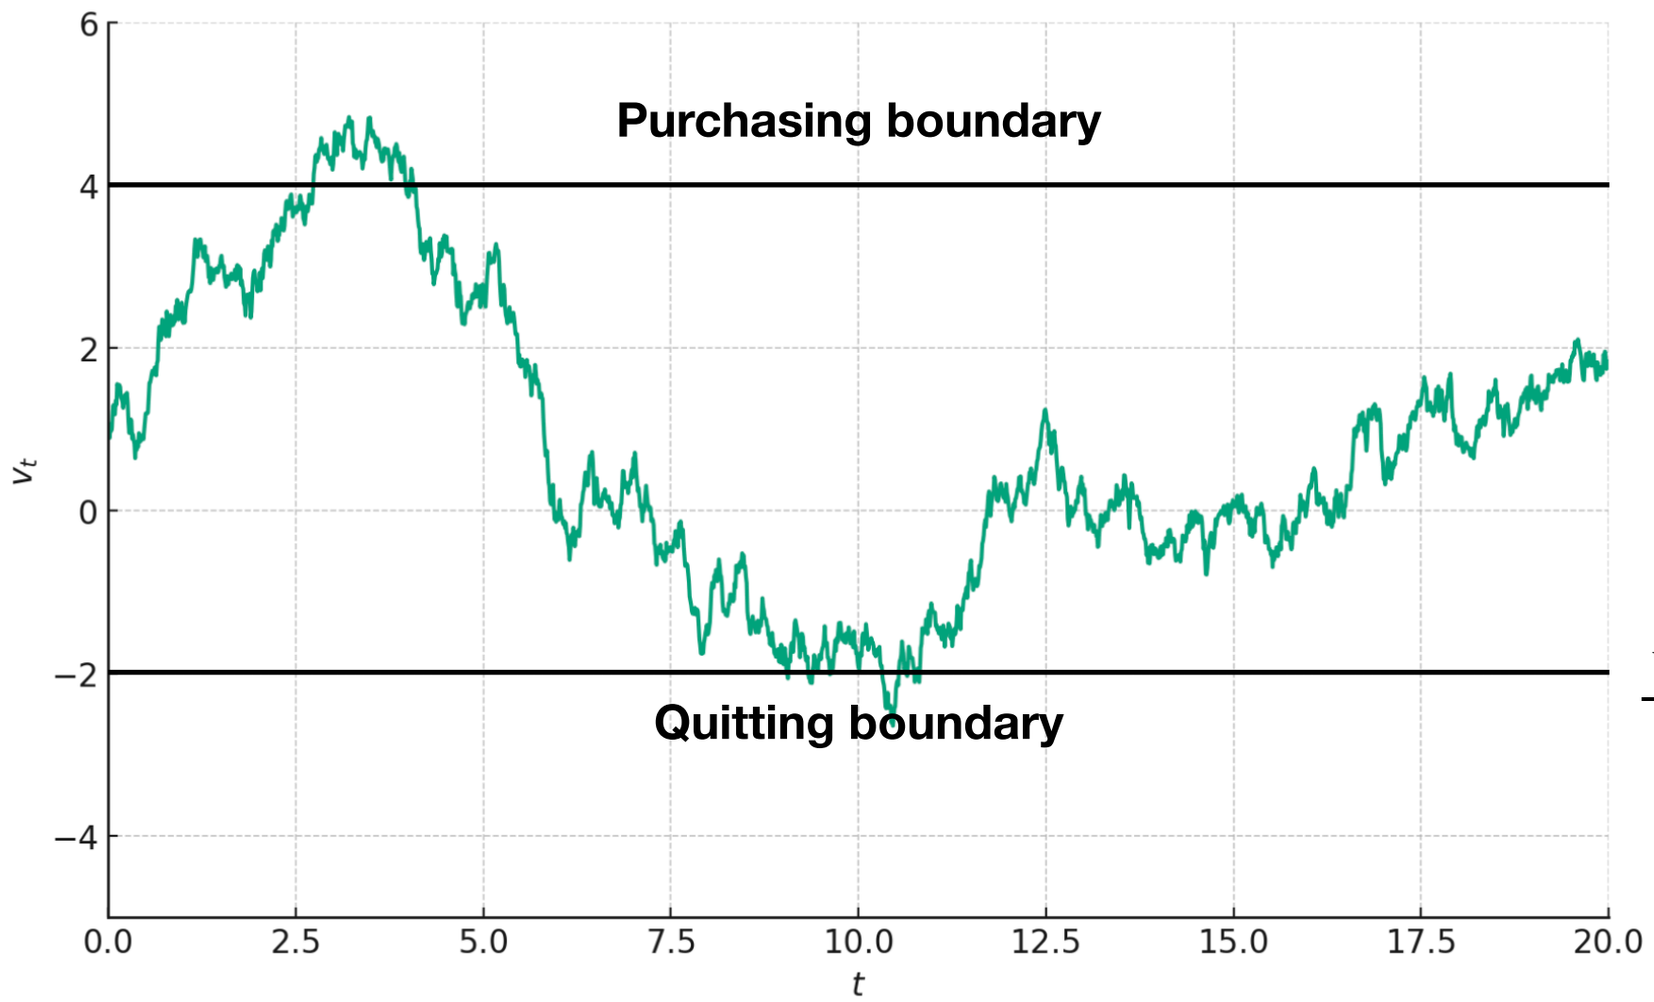
$\underline{V}_1(p) = -\sigma^2/4c + p$

$v_0 = 1,\ p = 1,\ c = 0.01,\ \sigma = 0.4$

Higher learning speed/lower search cost expands the search region



Lower learning speed/higher search cost shrinks the search region



$\bar{V}_1(p) = \sigma^2/4c + p$

$\underline{V}_1(p) = -\sigma^2/4c + p$

Consumer search can benefit the firm

Without consumer search: market does not exist

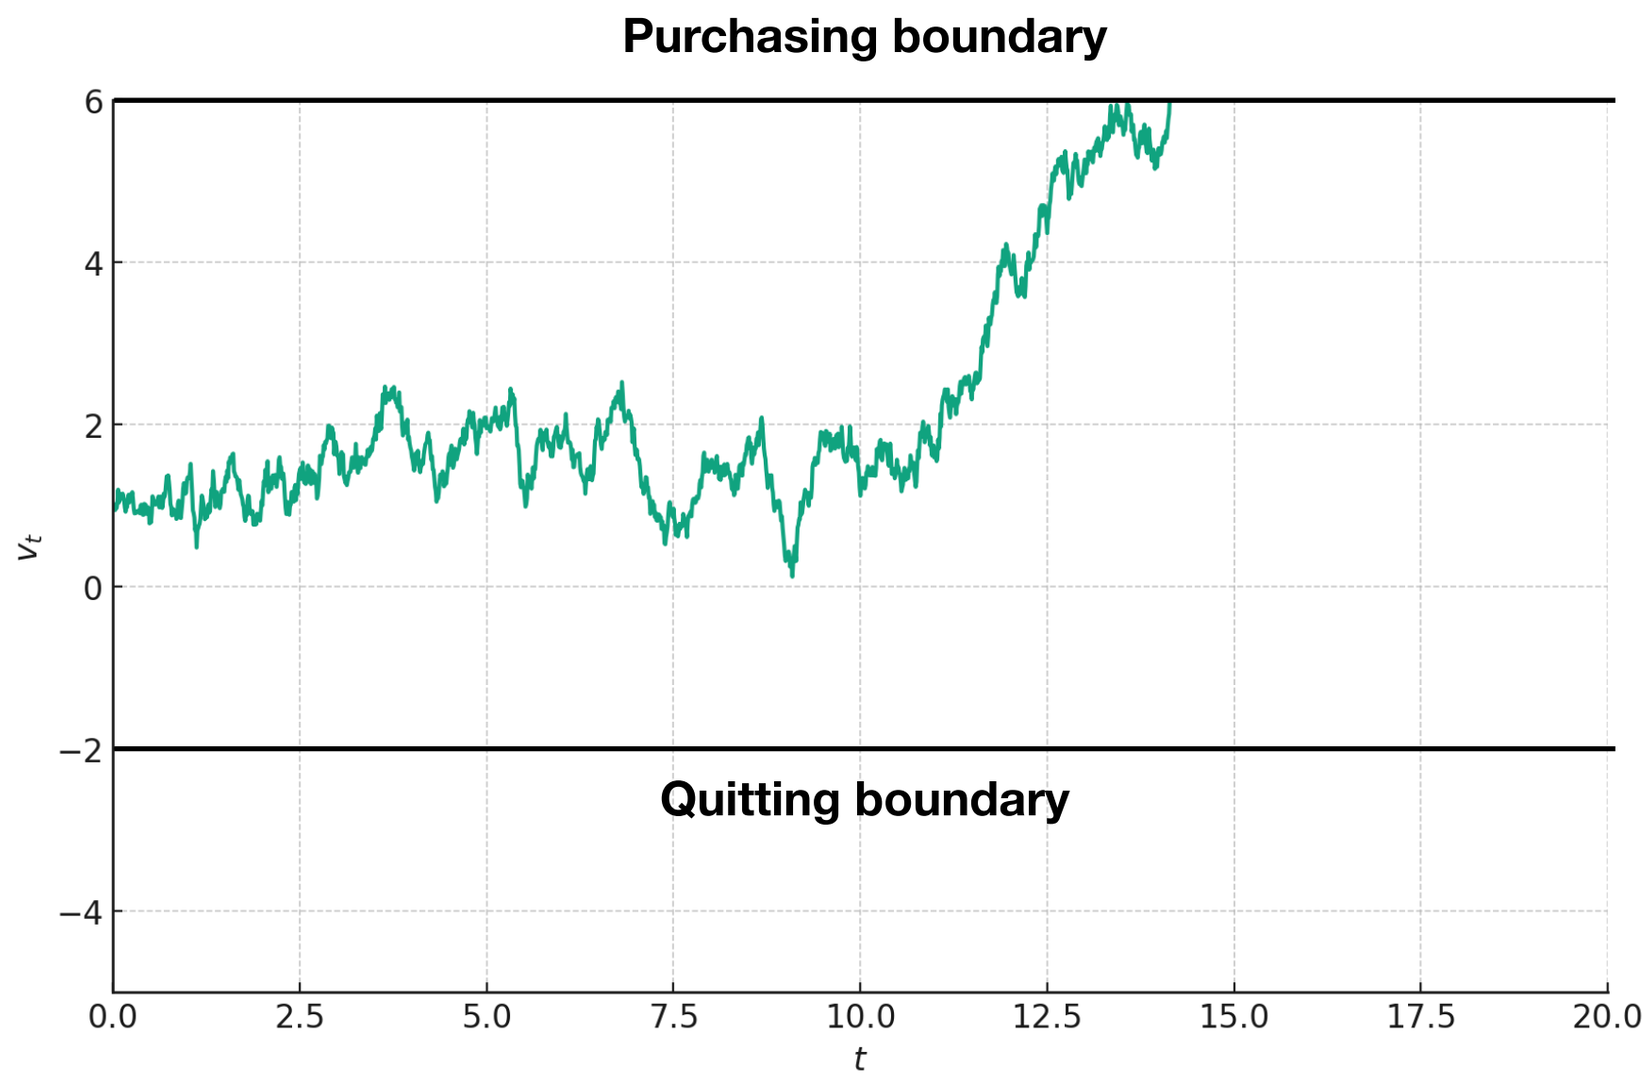
- $v_0 = 1 < m = 1.5$:

Consumer will buy if $p \leq 1$

Firm will sell if $p \geq 1.5$

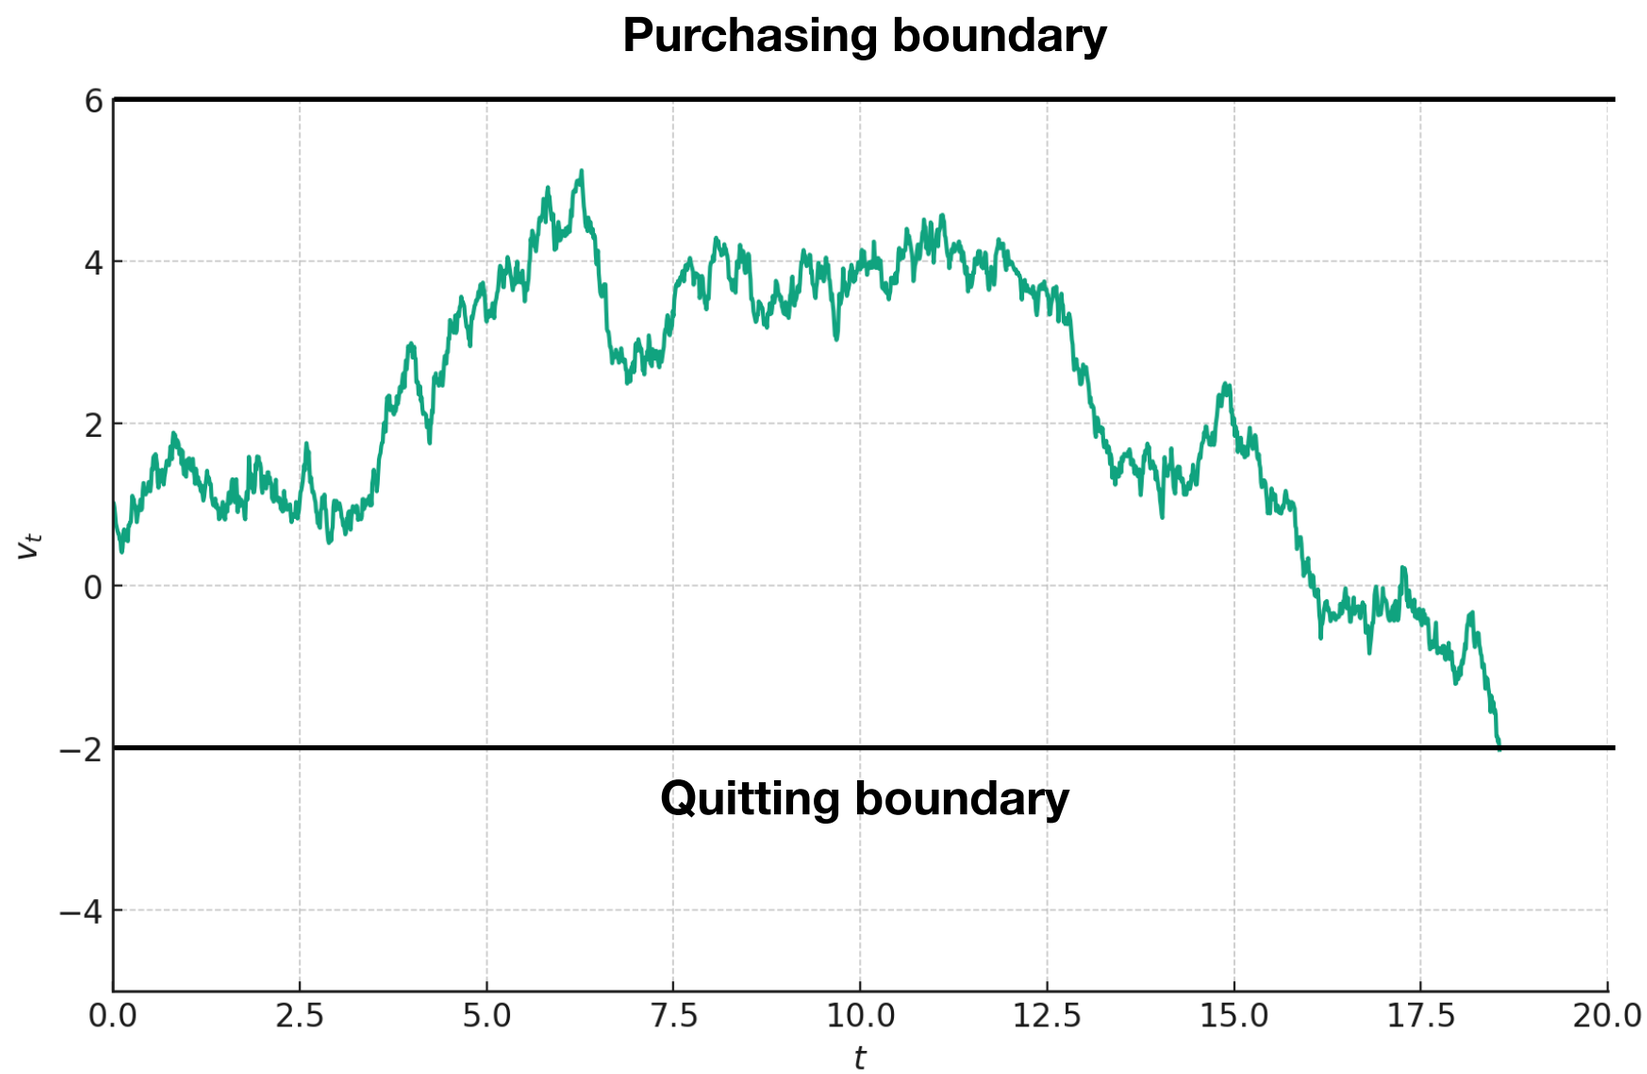
$\Rightarrow$ No market

With consumer search: purchase



$v_0 = 1,\ m = 1.5,\ p = 2$

With consumer search: no purchase



$v_0 = 1,\ m = 1.5,\ p = 2$

Consumer search can benefit the firm

- When search is not feasible, the firm can charge at most v_0

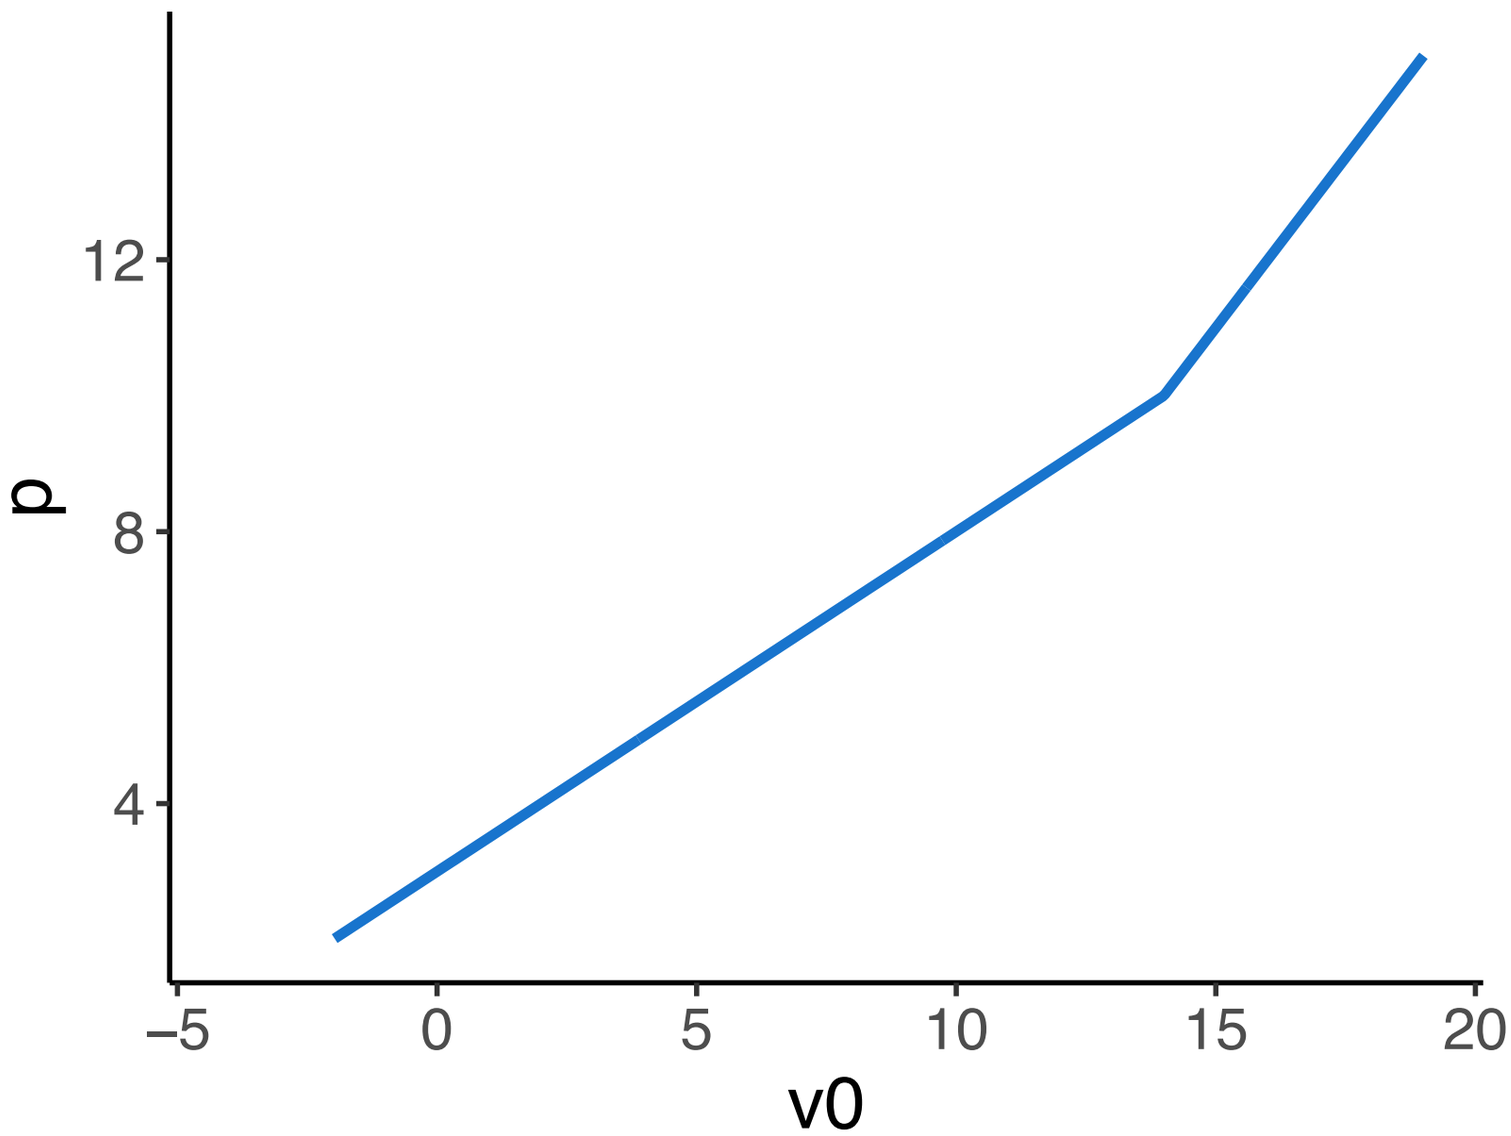
The firm will not sell any product if the initial valuation is lower than the marginal cost, $v_0 < m$

- When search is feasible, the firm can charge a higher price

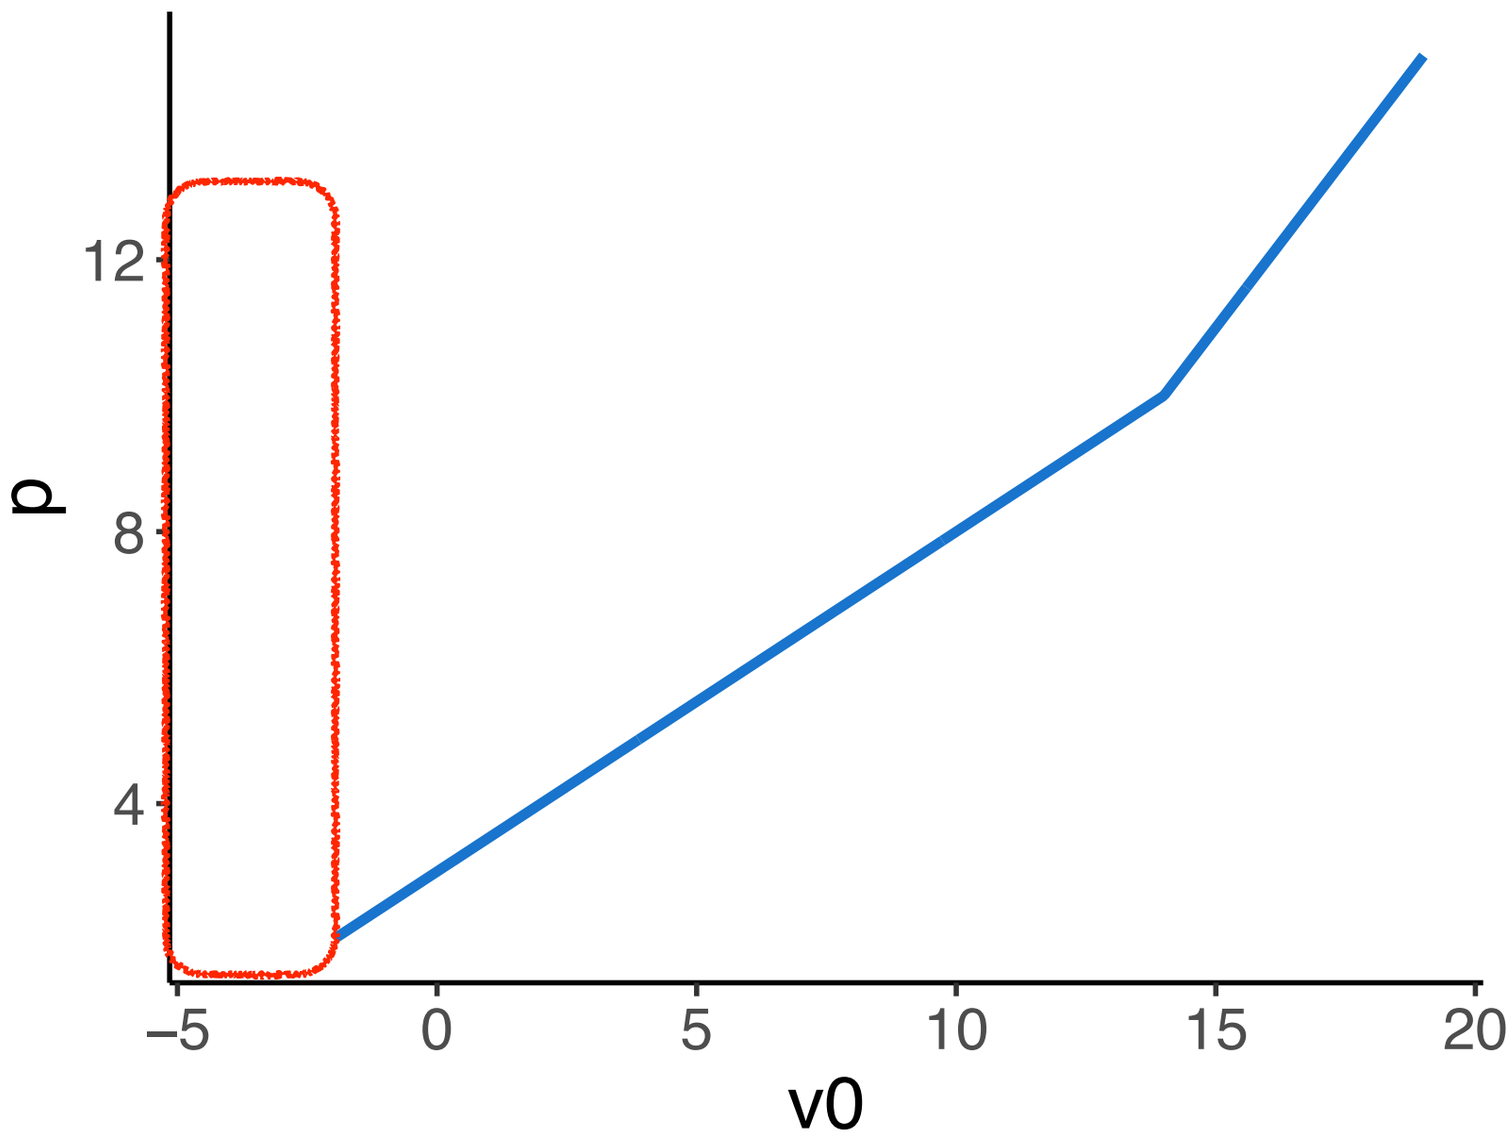
The firm can make positive profits even if $v_0 < m$

Equilibrium without a hidden fee (with consumer search)

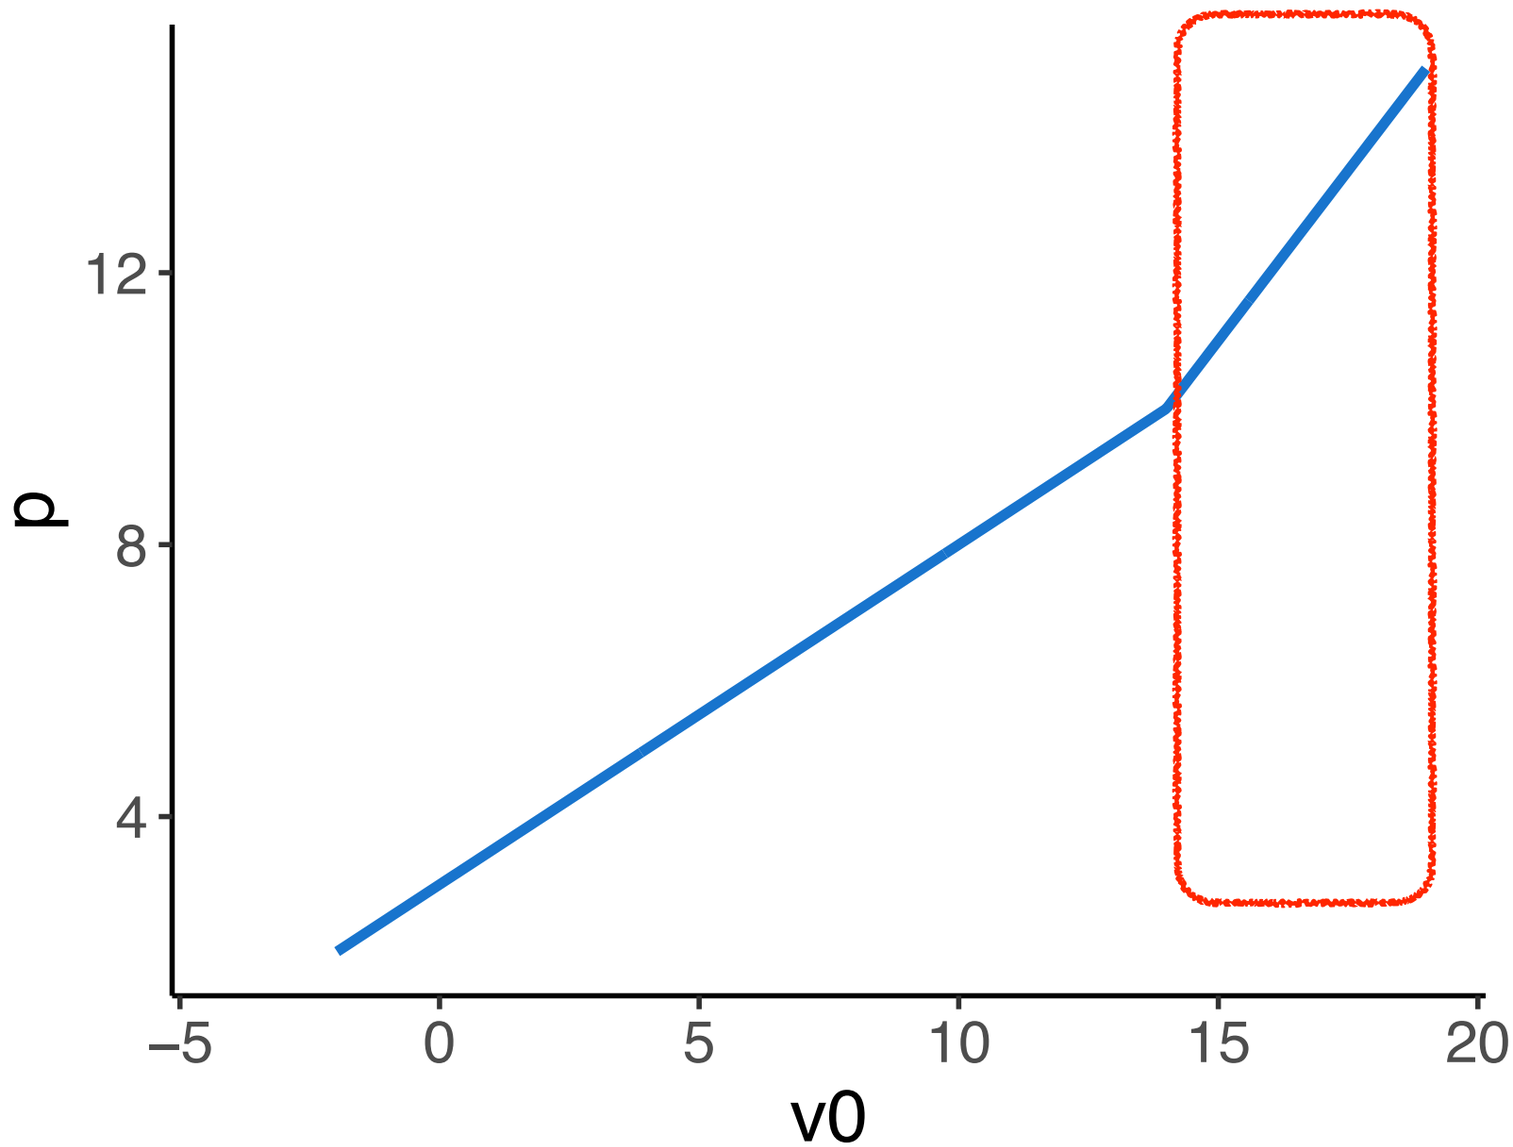
Optimal price



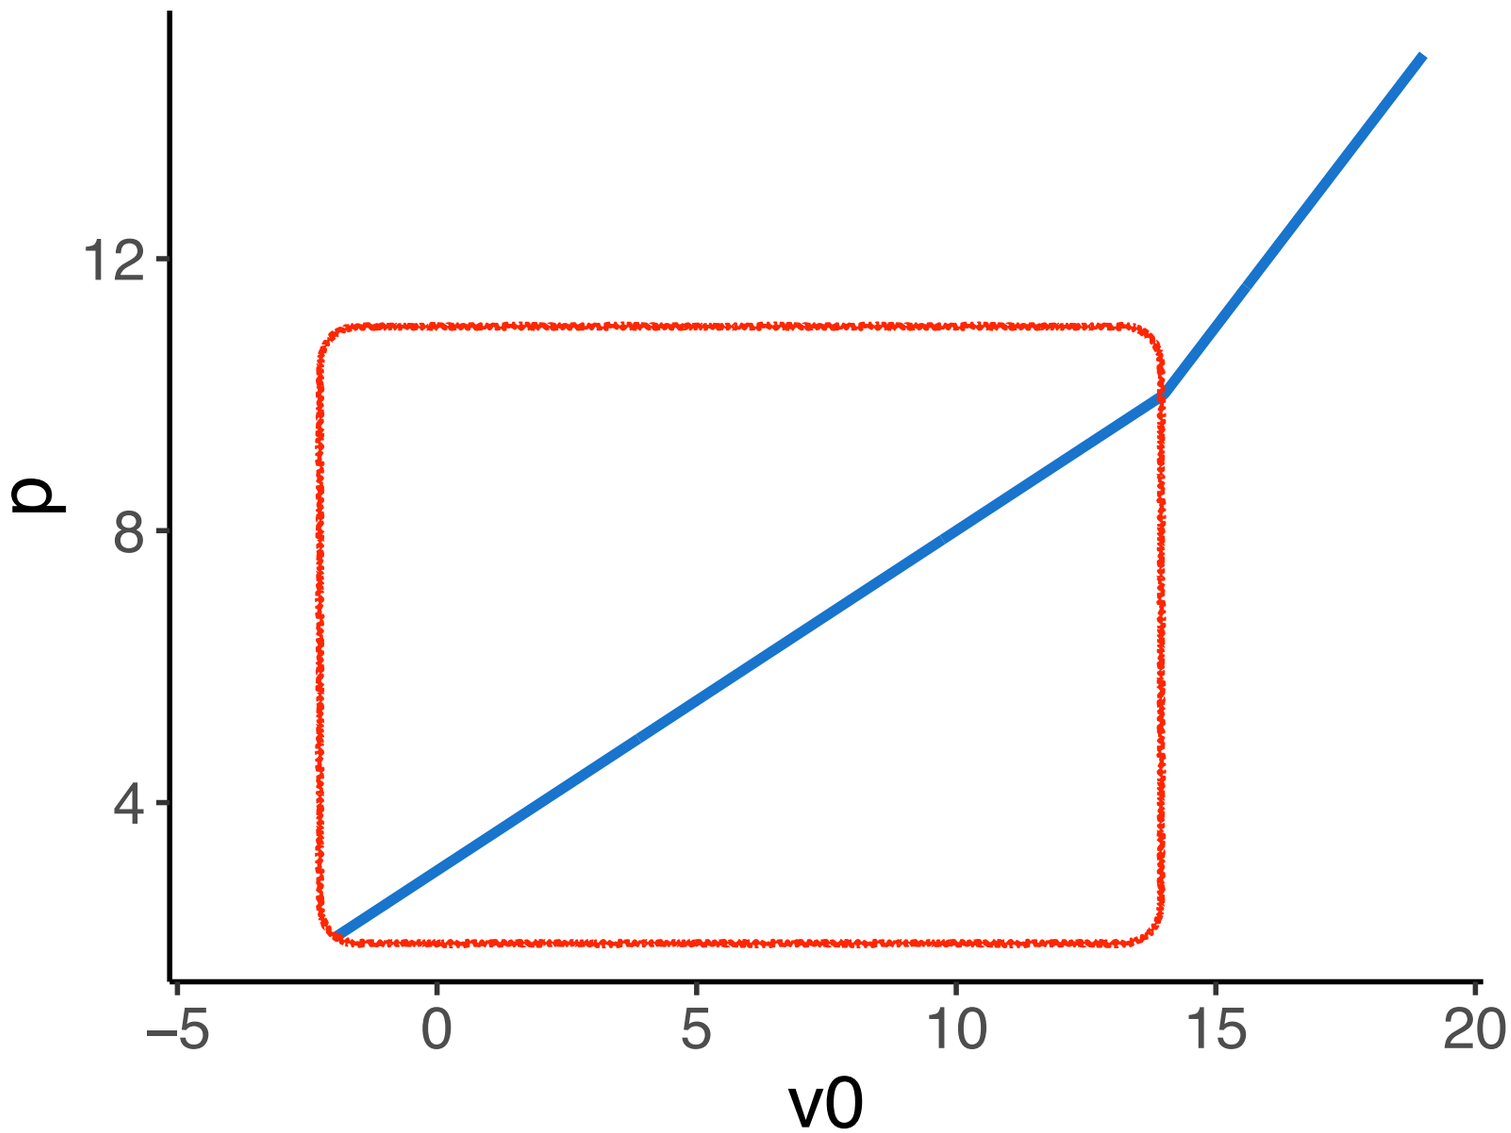
Optimal price - inducing direct quit



Optimal price - inducing immediate purchase



Optimal price - inducing search



Expected search time and consumer welfare

- $v_0 \leq -\frac{\sigma^2}{4c} + m$ (quit directly):

0 search time τ_{wo}, 0 consumer welfare

- $v_0 \geq \frac{3\sigma^2}{4c} + m$ (buy directly):

0 search time, consumer welfare is $v_0 - p^*_{wo} = \sigma^2/4c$

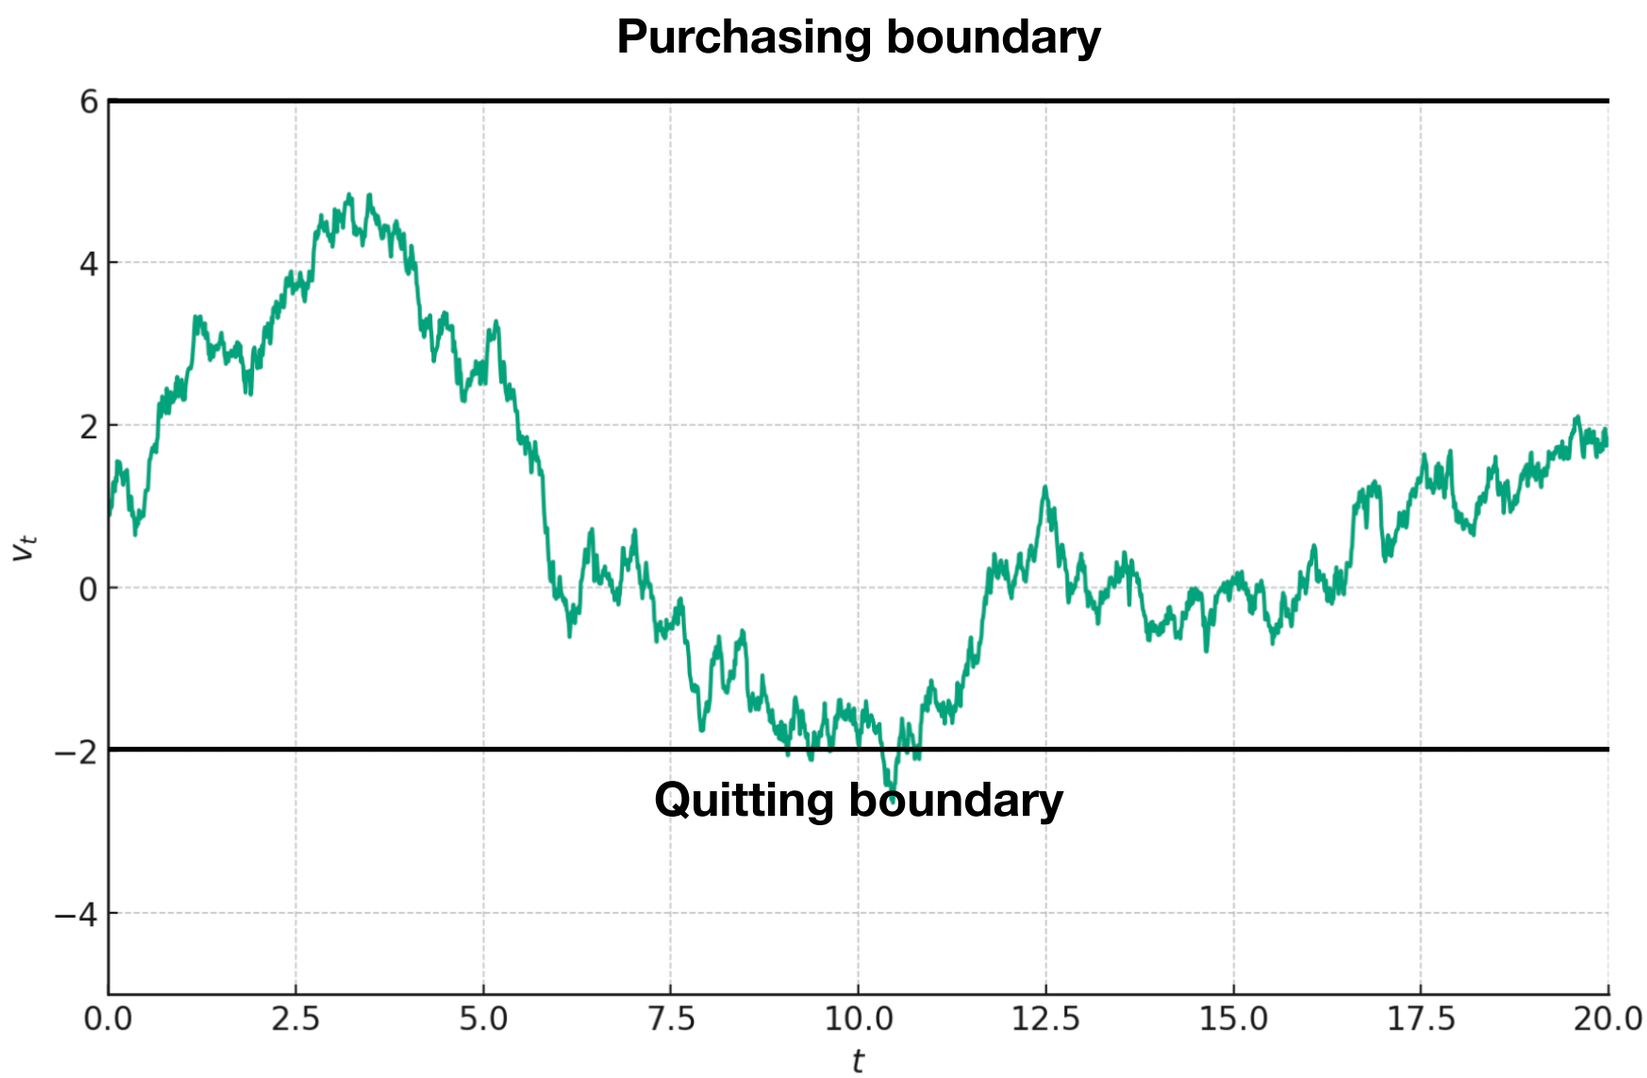
Expected search time and consumer welfare

- $-\frac{\sigma^2}{4c} + m < v_0 < \frac{3\sigma^2}{4c} + m$ (search): Dynkin's formula $\Rightarrow$

$$\mathbf{E}(search\ time) = \frac{\frac{\sigma^4}{16c^2} - (v_0 - p^*_{wo})^2}{\sigma^2}$$ (**maximized when** $p^*_{wo} = v_0$)

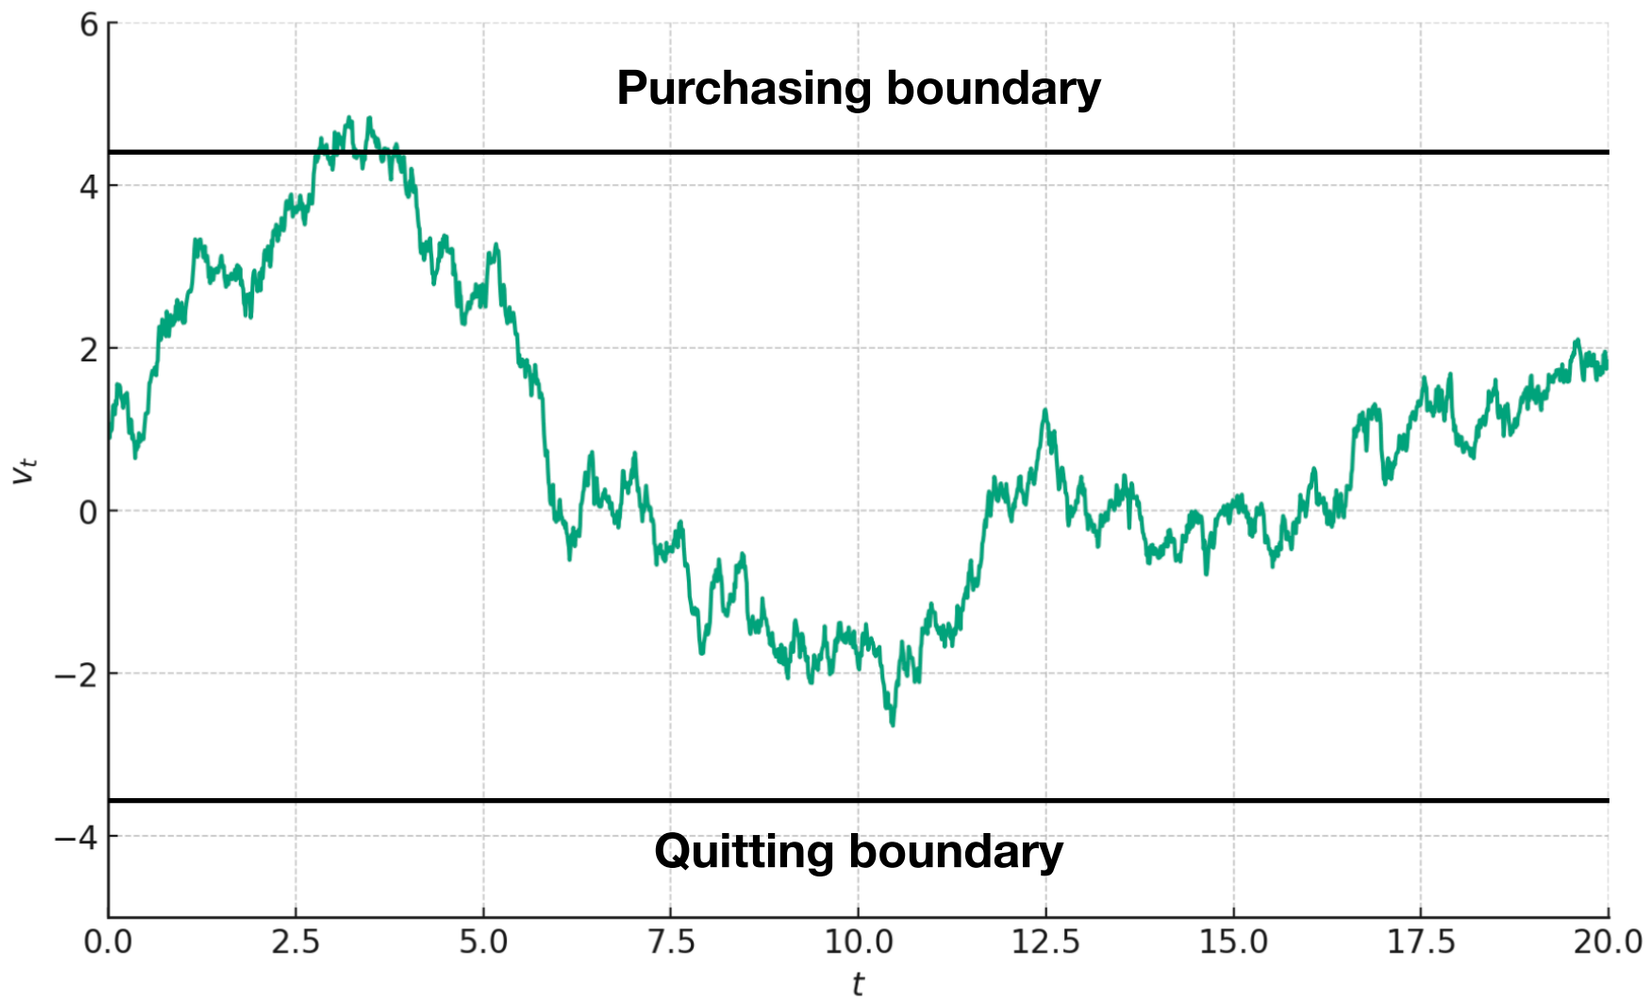
$$\mathbf{E}(consumer\ surplus) = -\,c \cdot \mathbf{E}(search\ time) + \frac{\sigma^2}{4c} \cdot Purchasing\ probability$$

Expected search time



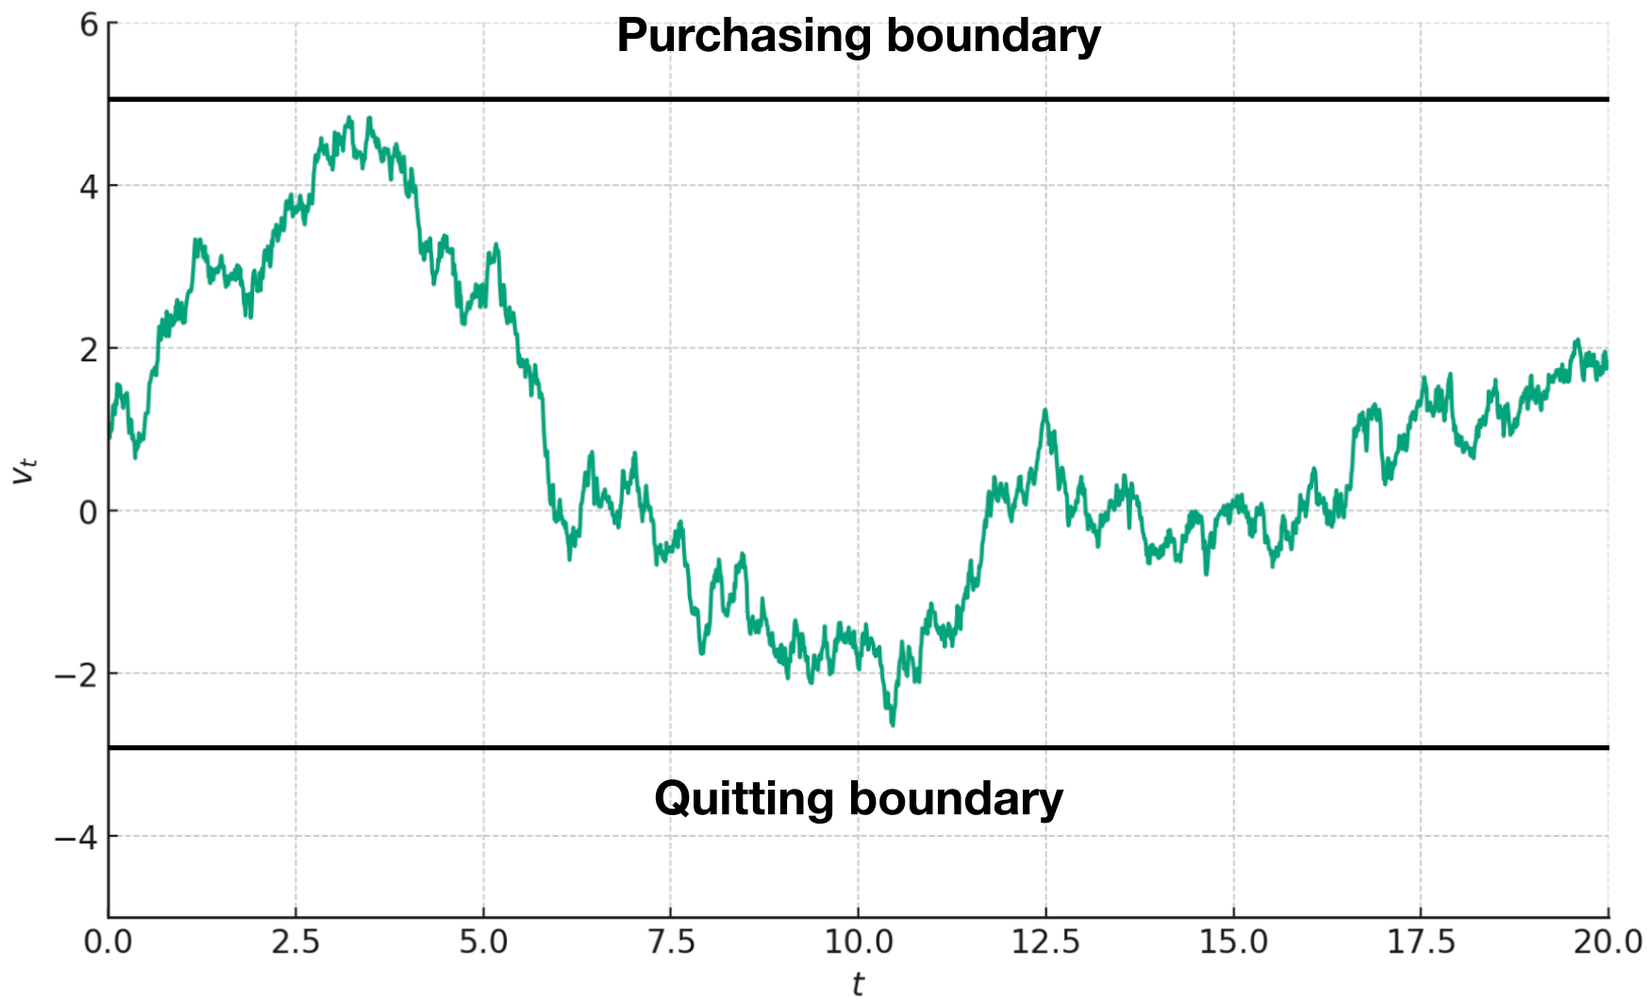
$v_0 = 1,\ p = 2$

Expected search time



$v_0 = 1,\ p = 0.5$

Expected search time



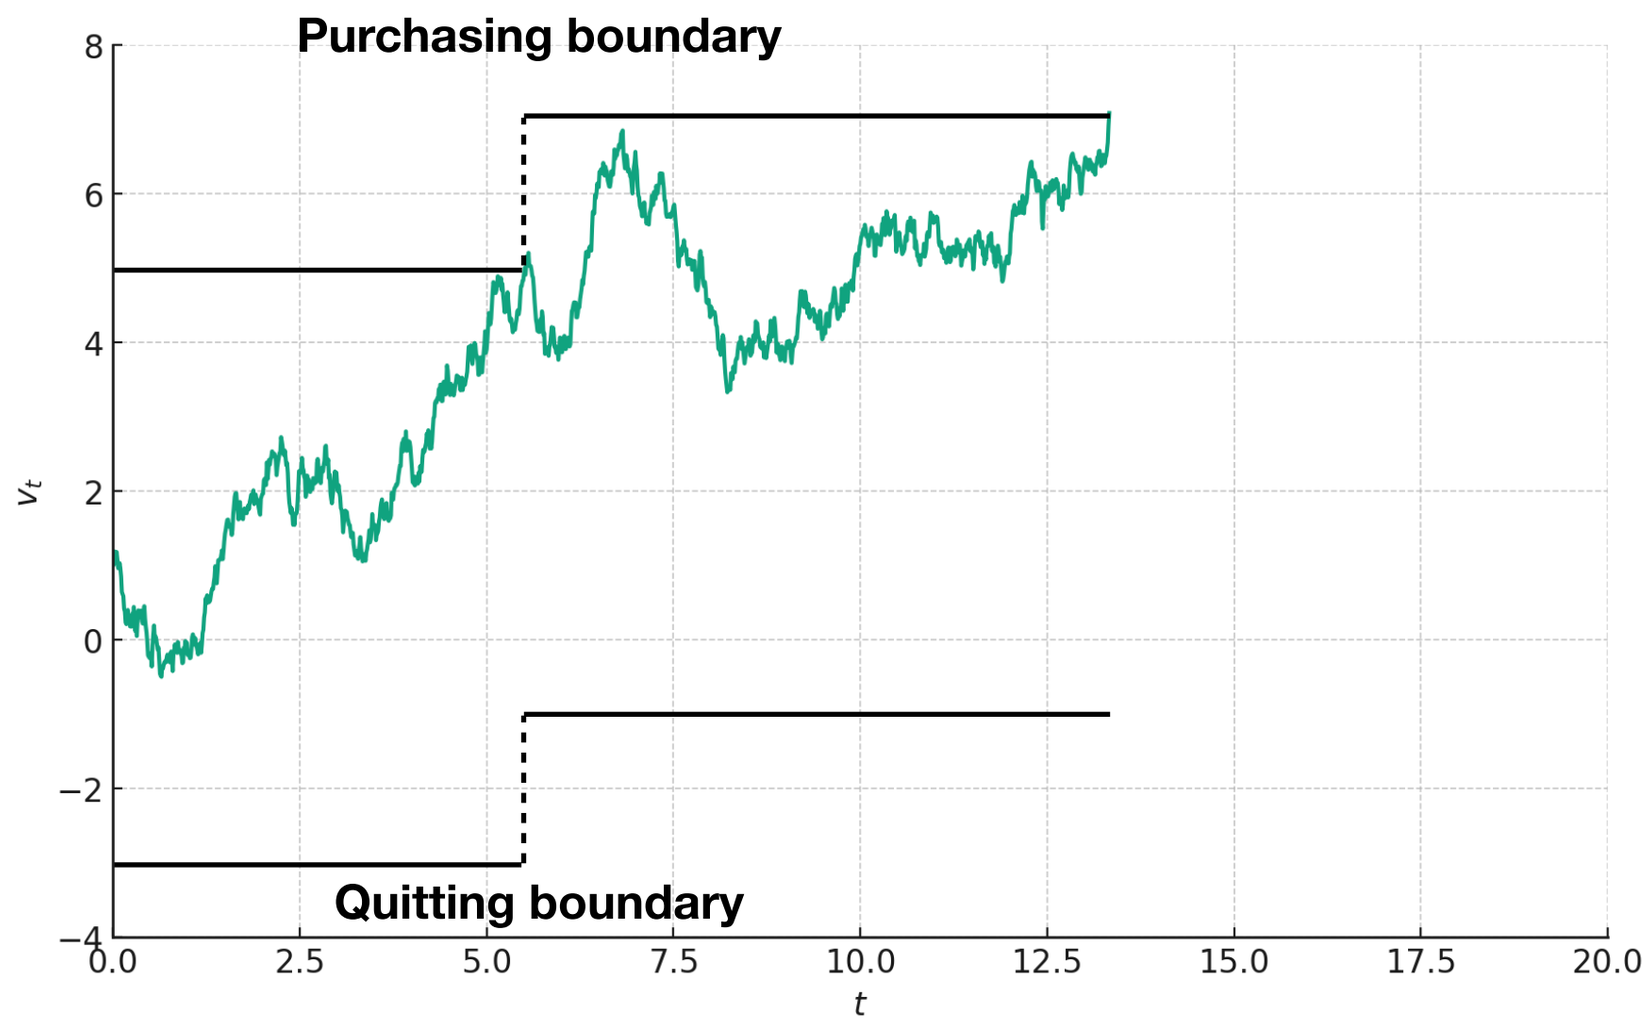
$v_0 = 1,\ p = 1$

Equilibrium with a hidden fee (with consumer search)

+ Hidden fee

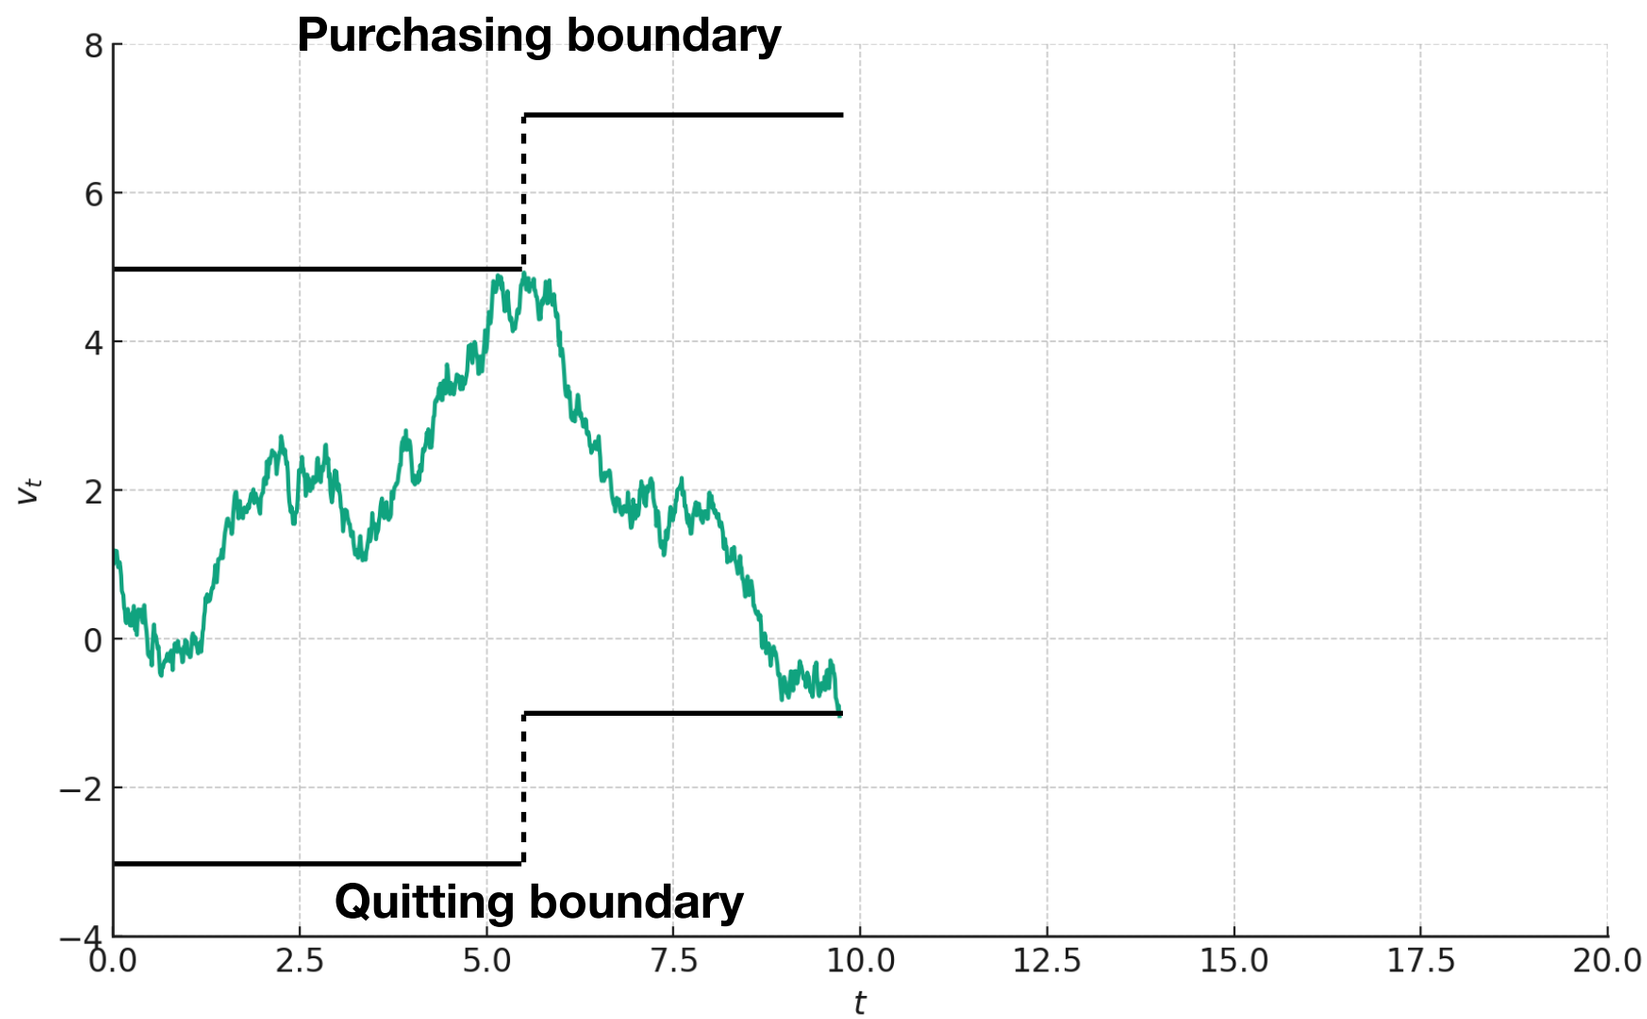
- The same setup as before, except that:
- When a consumer's valuation v_t reaches the purchasing threshold, she
  - decides to buy and go to the checkout page
  - will see an additional hidden fee Δp
  - will not buy the product (the hidden fee raises the purchasing threshold)
  - faces an updated search problem

Sample search path (purchase)



$v_0 = 1,\ m = 1.5,\ p = 1,\ \Delta p = 2$

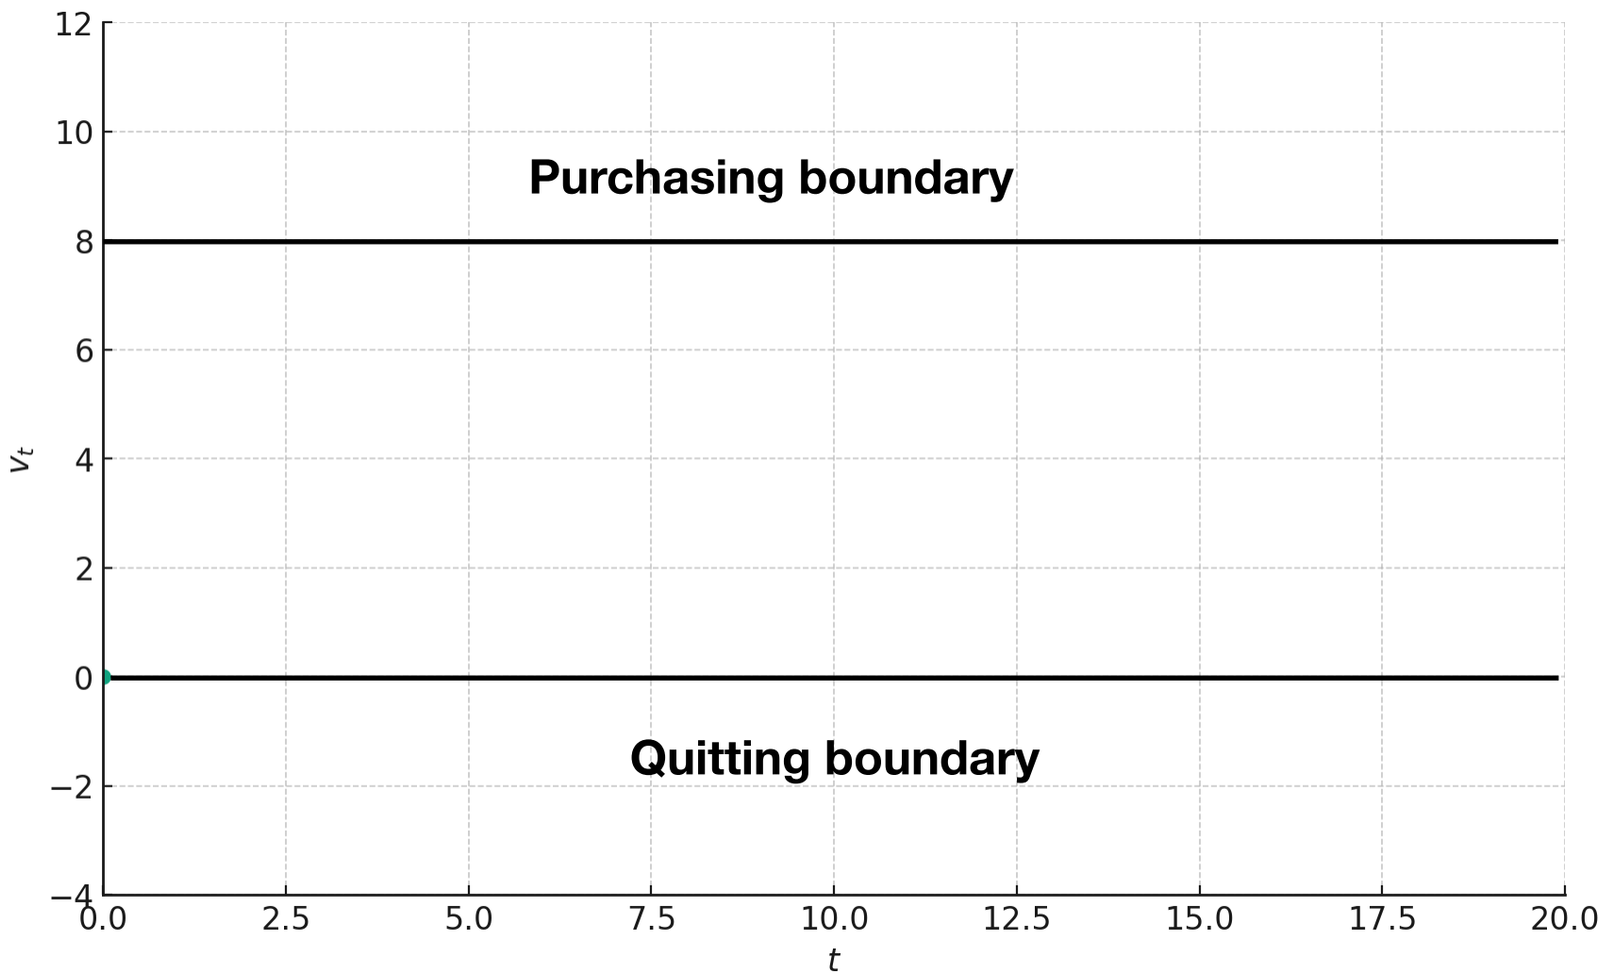
Sample search path (no purchase)



$v_0 = 1,\ m = 1.5,\ p = 1,\ \Delta p = 2$

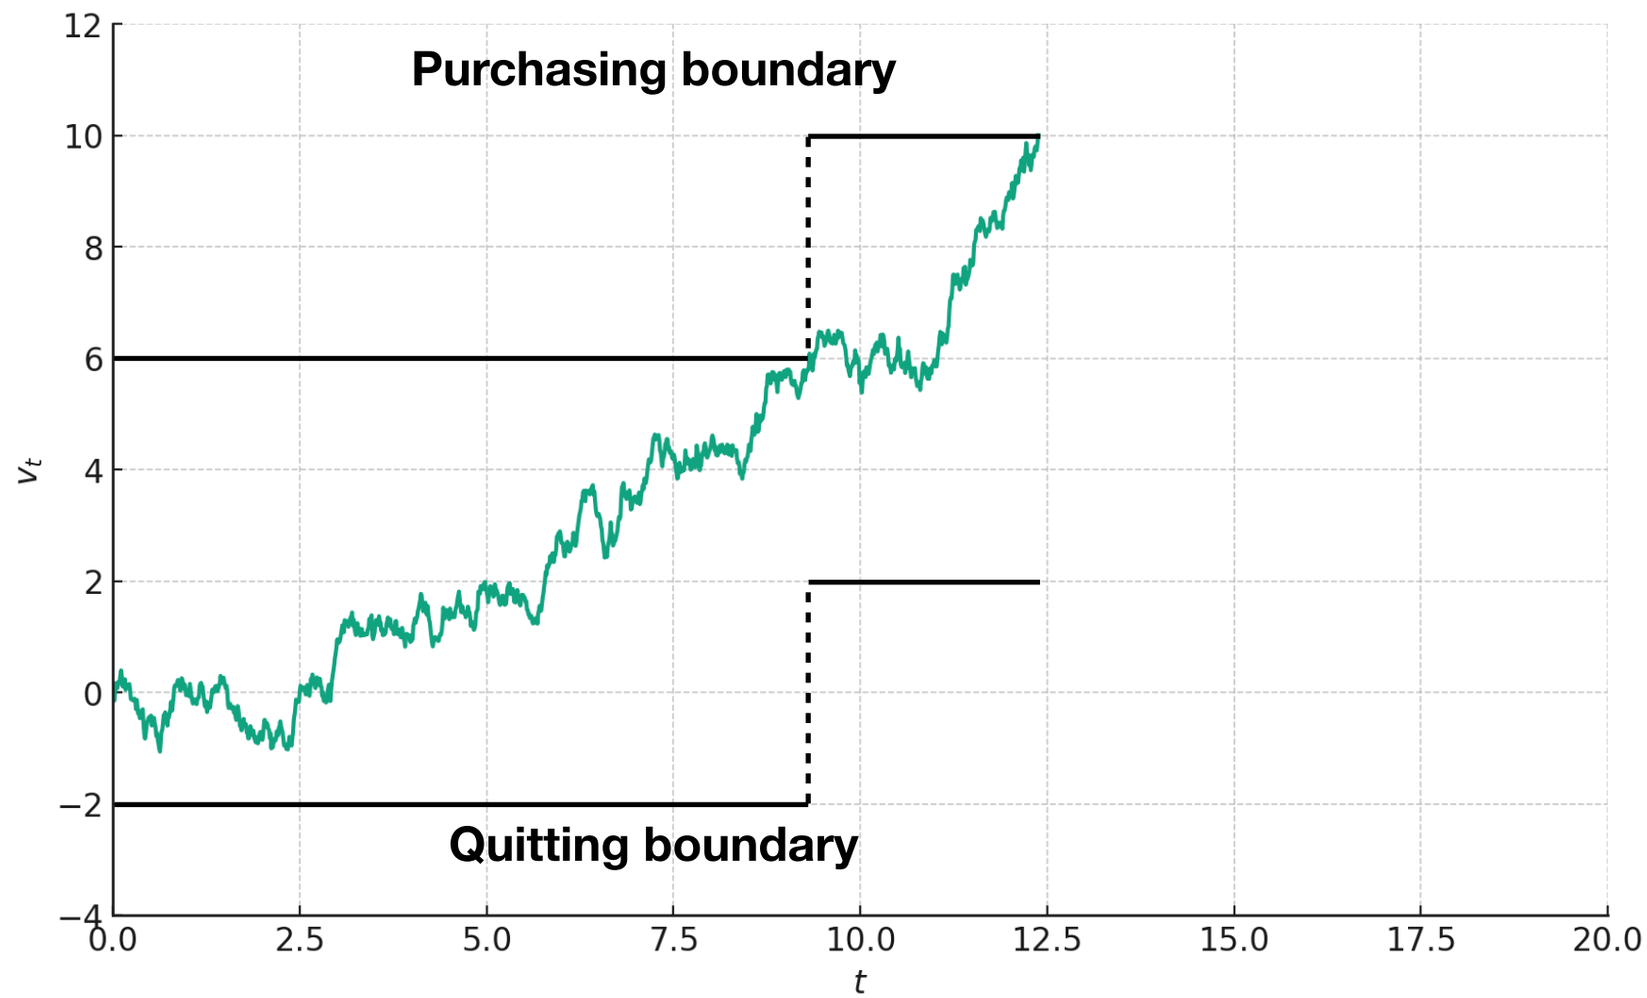
Hidden fees can benefit the firm

Neither search nor purchase without a hidden fee



$v_0 = 0,\ m = 4,\ p = 4$

Positive expected profit with a hidden fee



$v_0 = 0,\ m = 4,\ p_1 = 2,\ \Delta p = 4$

Hidden fees can benefit the firm

- When hidden fee is not feasible, the consumer may search or buy directly only if $v_0 > p - \sigma^2/4c$

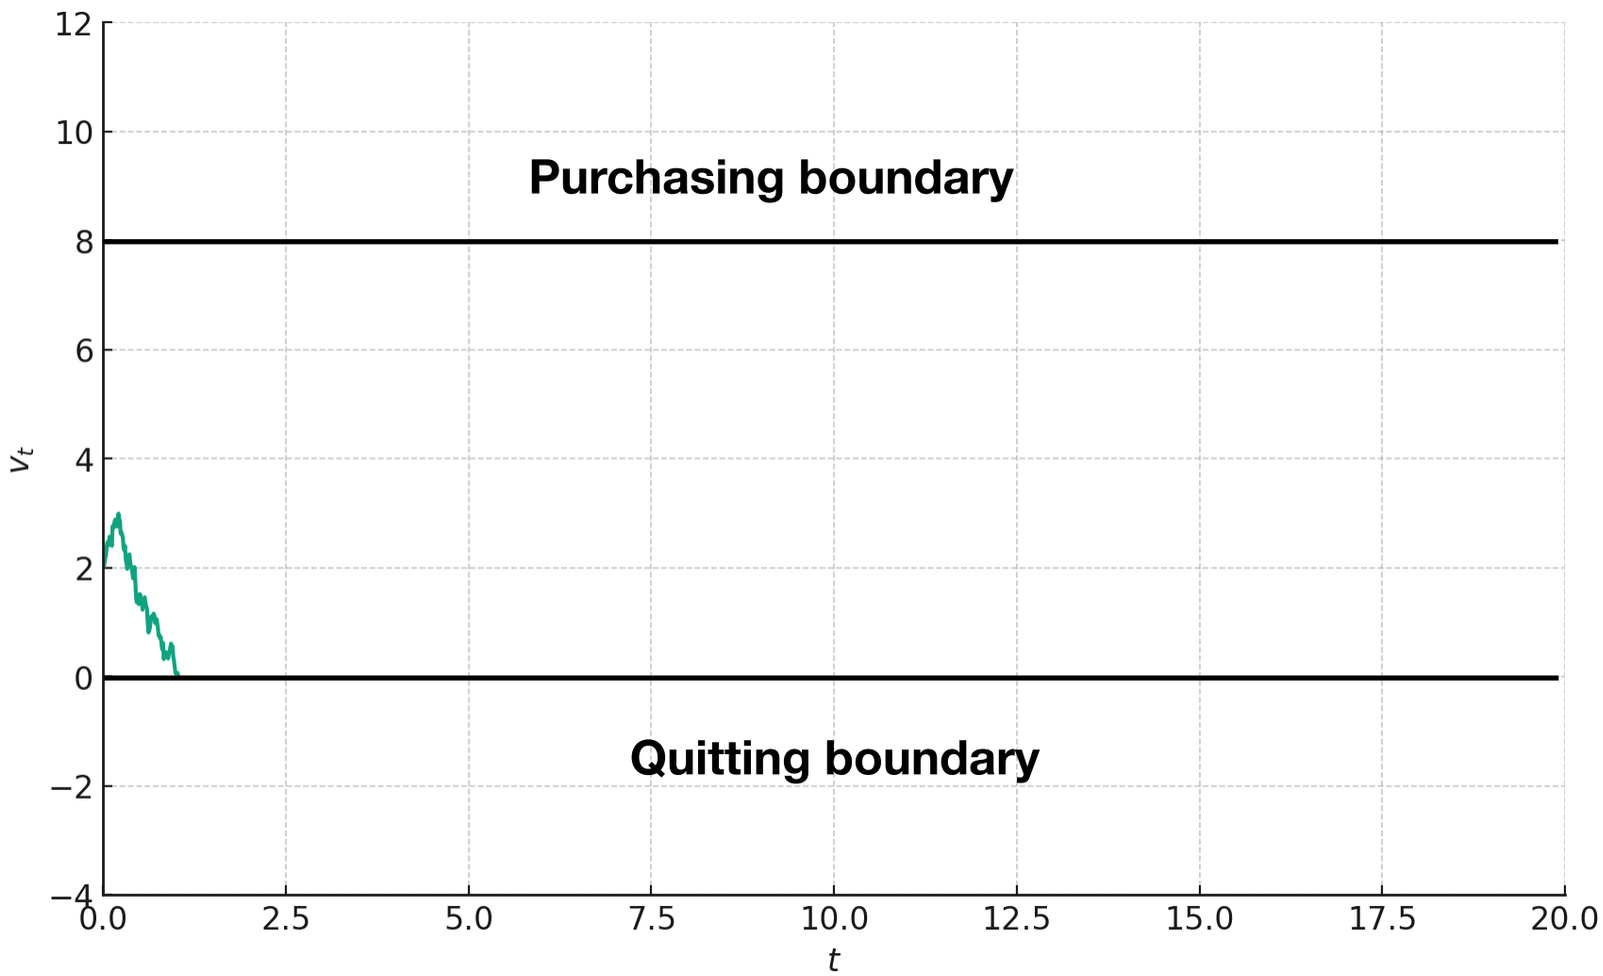
- To earn a profit, price must be higher than marginal cost p > m

The firm will not sell any product if $v_0 < -\sigma^2/4c + m$

- When hidden fee is feasible, the firm can induce the consumer to search in a wider range by offering a lower price initially

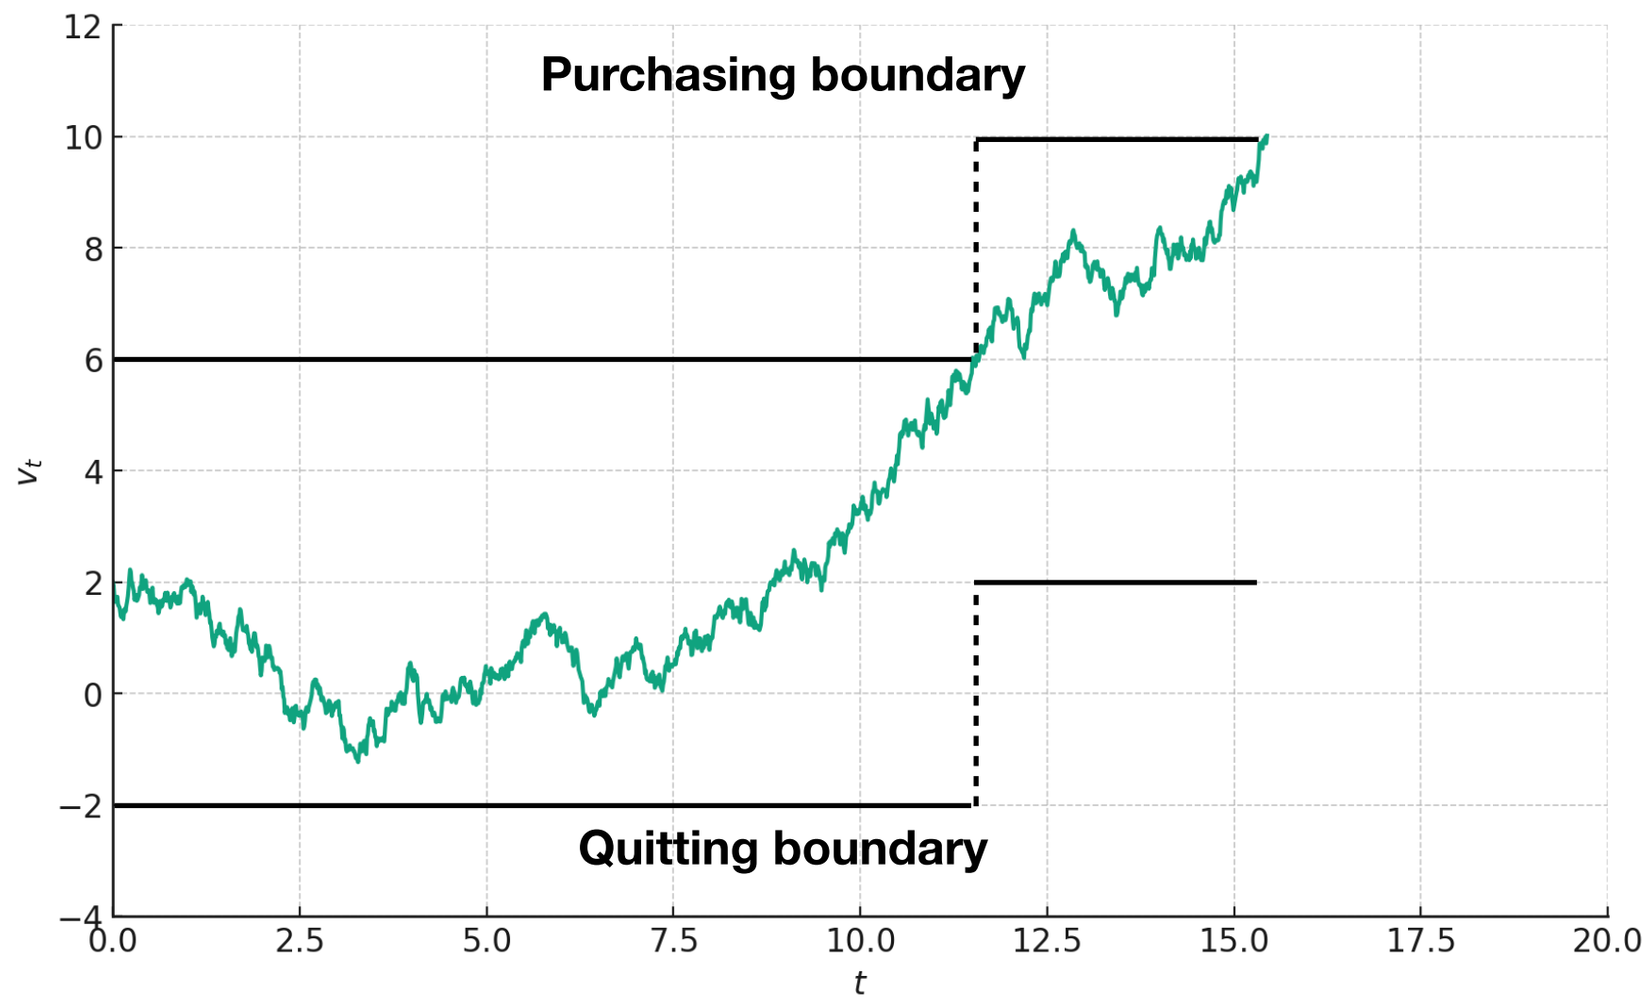
The firm can make positive profits even if $v_0 < -\sigma^2/4c + m$

Quick exit after searching without a hidden fee



$v_0 = 2,\ m = 2,\ p = 4$

Purchase after searching with a hidden fee



$v_0 = 2,\ m = 2,\ p_1 = 2,\ \Delta p = 4$

Hidden fees can benefit the firm

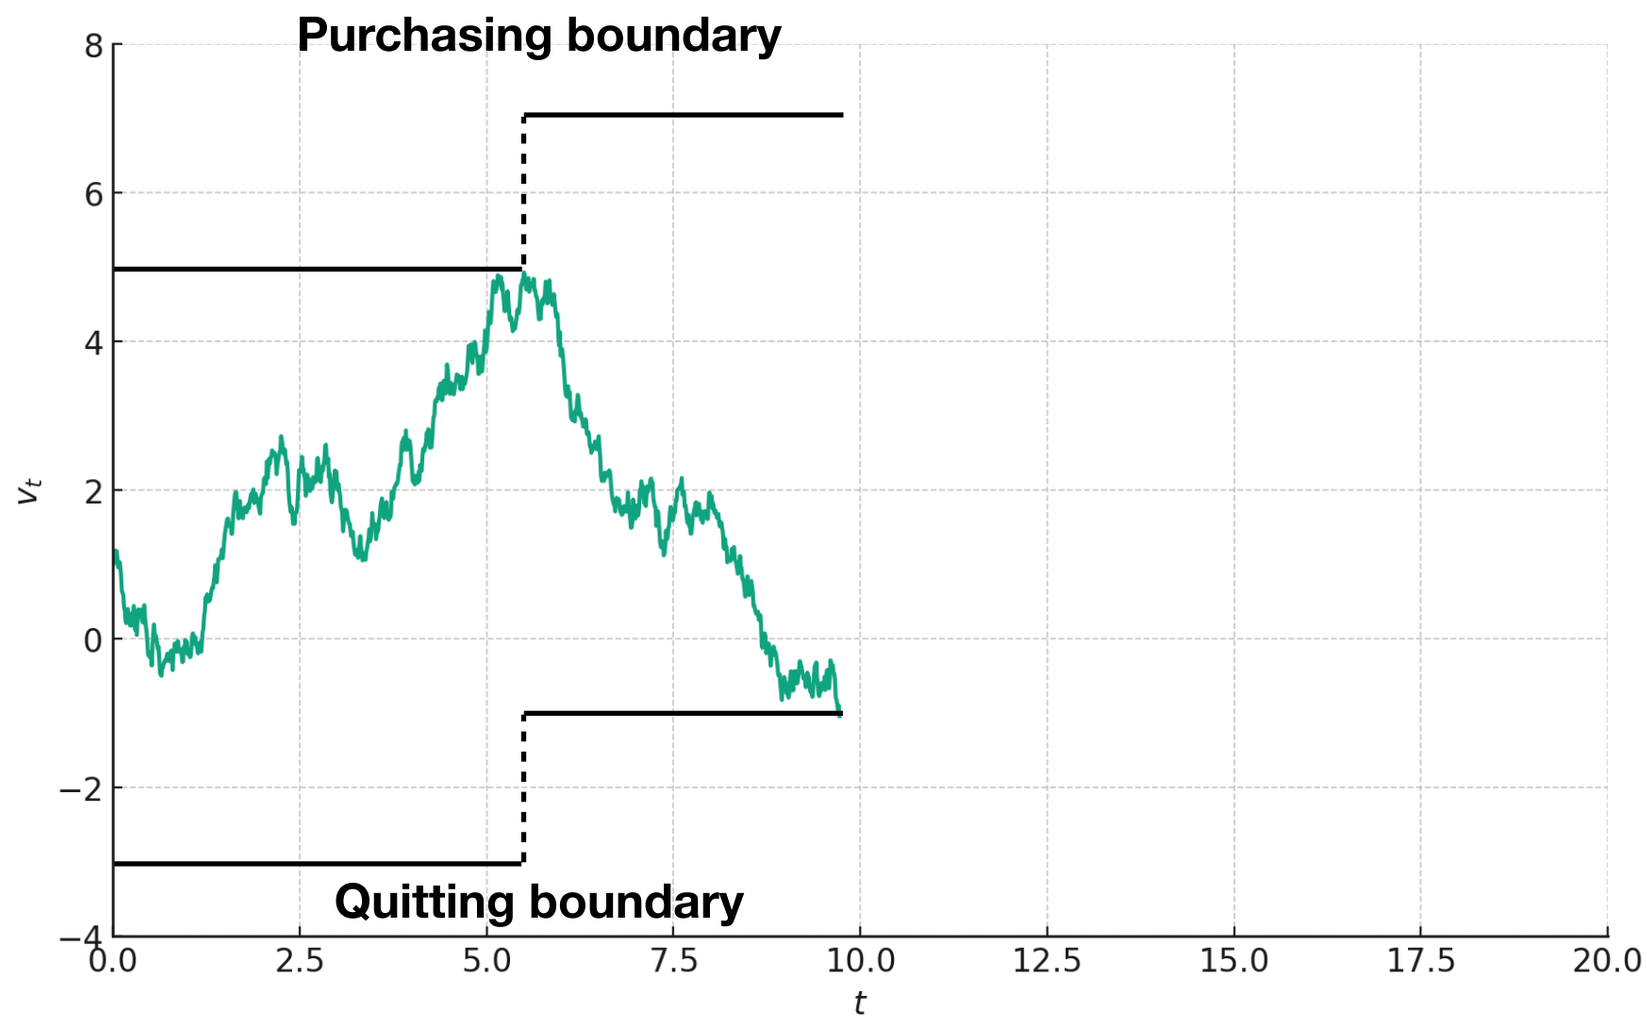
- Even if the firm can earn a positive profit without hidden fee when $v_0 > -\sigma^2/4c + m$, it can increase the profit by using hidden fee

$\Rightarrow$ induce consumers to continue searching in cases where early signals are unfavorable (more persistent in search)

- Parameter range: $-\sigma^2/4c + m < v_0 < 3\sigma^2/4c + m$

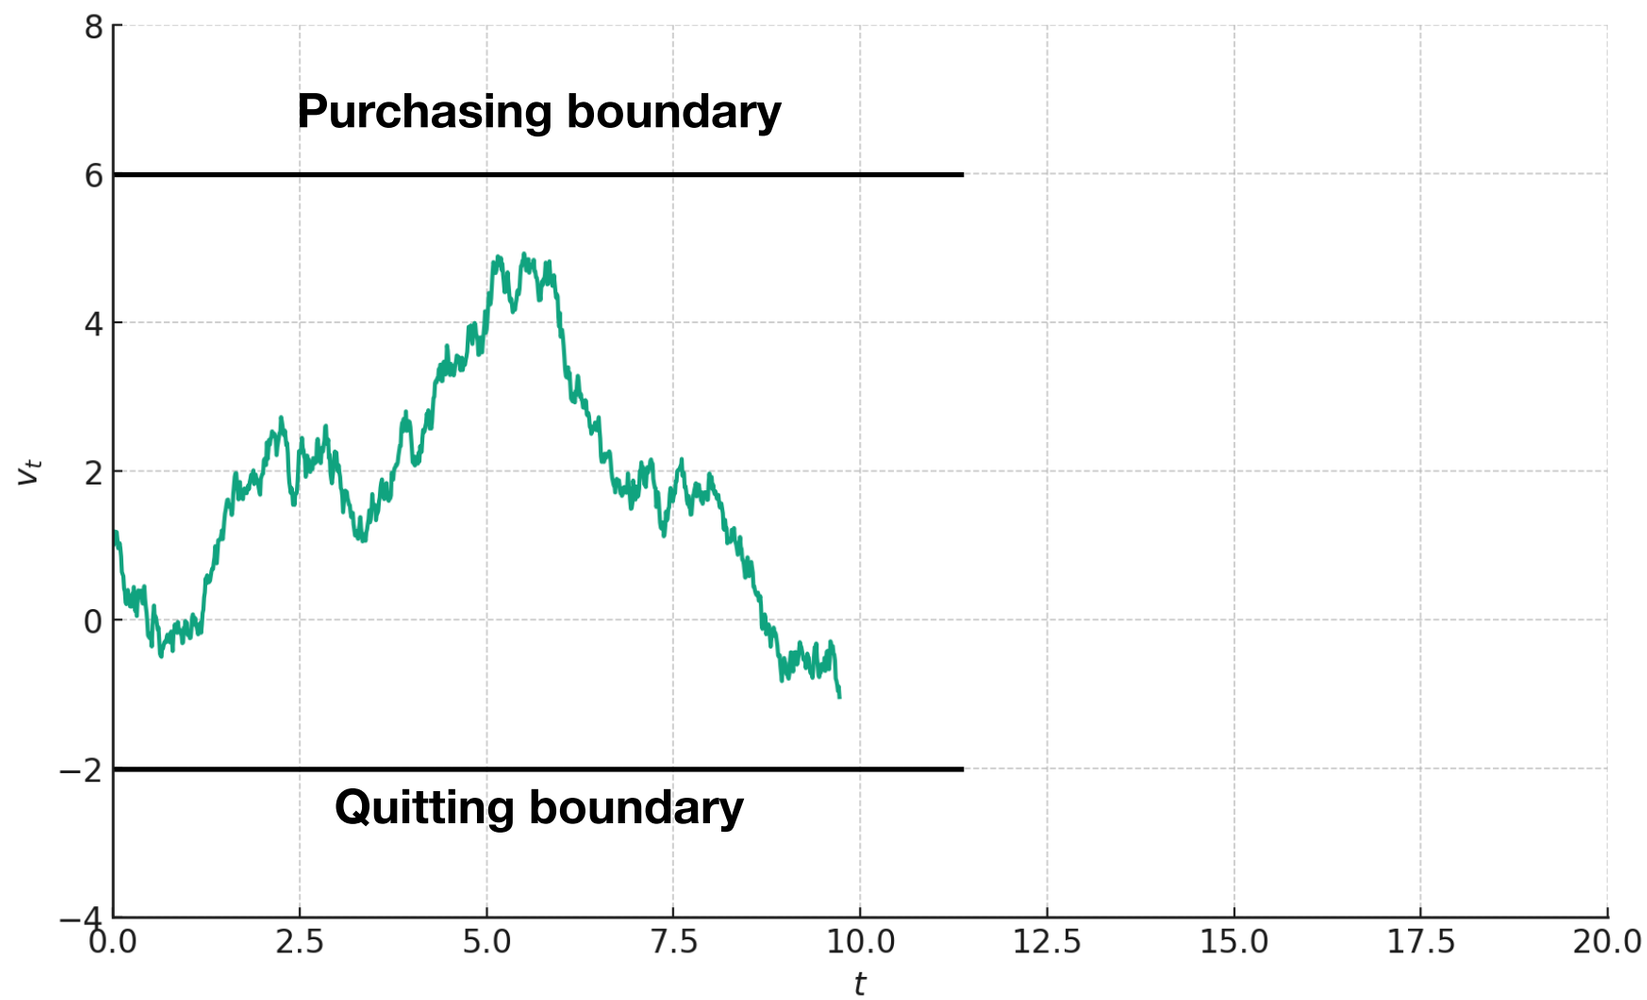
Hidden fees can hurt the firm

Quit under hidden fee



$v_0 = 1,\ m = 1.5,\ p = 1,\ \Delta p = 2$

Still searching under upfront price



$v_0 = 1,\ m = 1.5,\ p = 2$

Optimal price with a hidden fee

Expected search time induced by the optimal price

- Relatively high initial valuation v_0

$$\mathbf{E}(\tau_1) = \mathbf{E}(\tau_2)$$

The firm **perfectly smooths** consumers' search behavior across stages

- Intuition: (consider a fixed total price)

Initial price too high ⇒ quick exit if gathering a few negative signals early on ❌

Initial price too low 1) ⇒ go to the checkout stage with a high probability

2) ⇒ a high hidden fee ⇒ quick exit ❌

The optimal price balances consumers' incentives to continue search before and after fee disclosure

Expected search time induced by the optimal price

- Relatively low initial valuation v_0

$$\mathbf{E}(\tau_1) < \mathbf{E}(\tau_2)$$

- Intuition:

Low $v_0 \Rightarrow$ quitting boundary is close to v_0 even with a low initial price
$\Rightarrow$ quick exit if the consumer gathers a few negative signals

If a consumer reaches the checkout page $\Rightarrow$ a much higher valuation
$\Rightarrow$ willing to keep searching even if she receives some negative signals

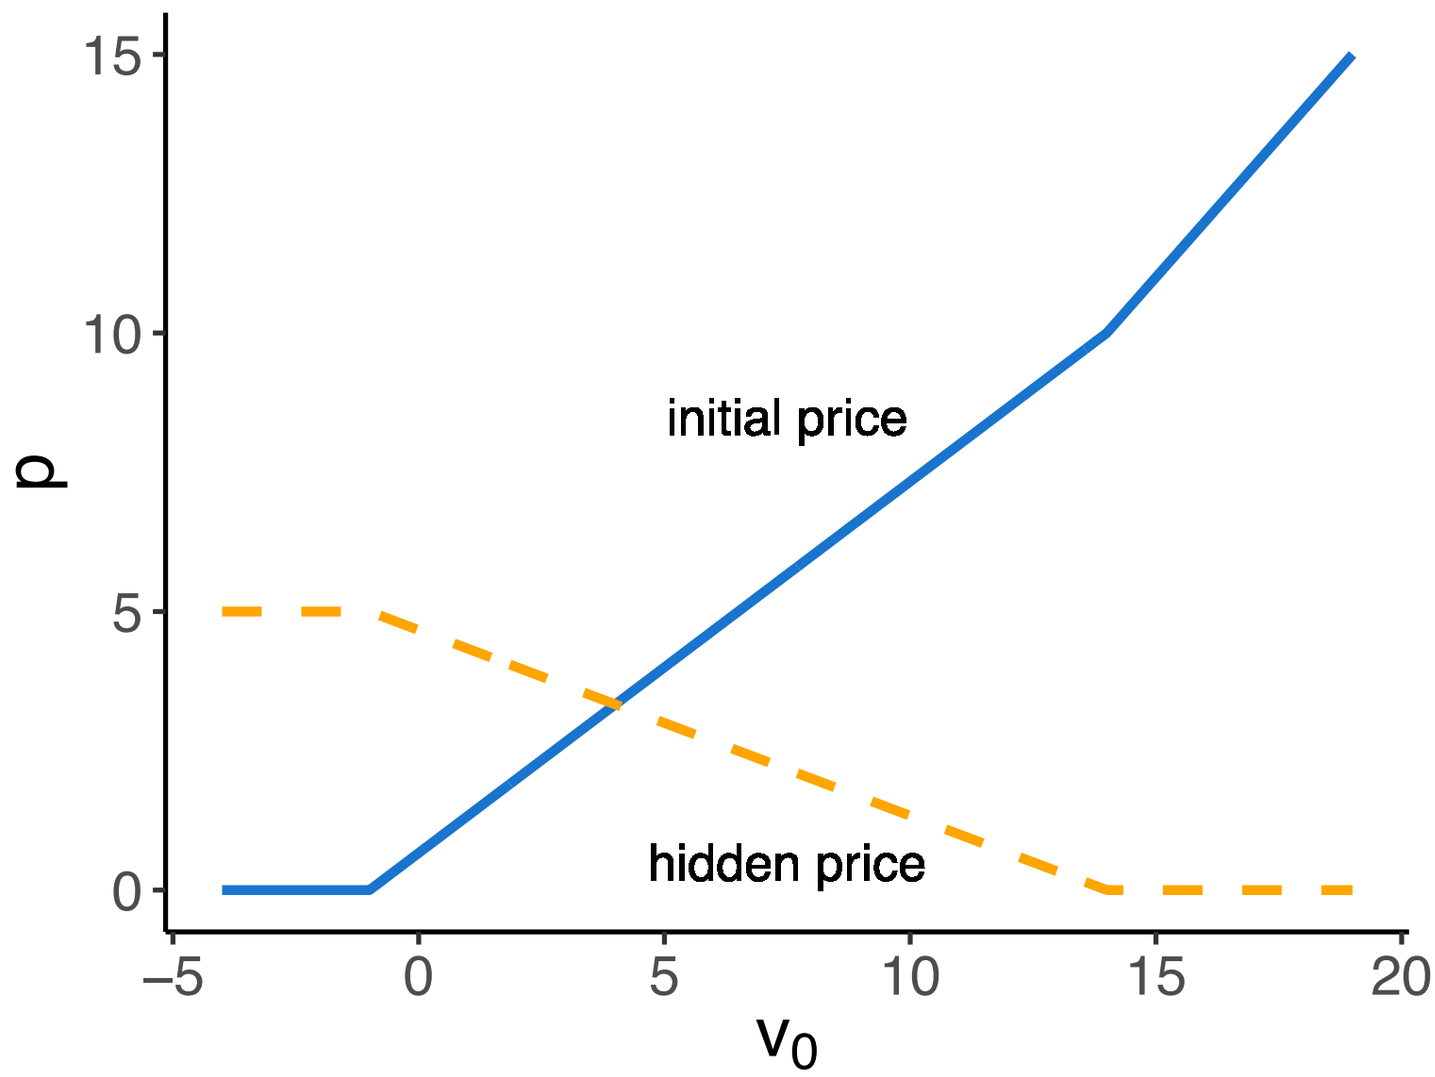
Impossible for the firm to perfectly smooth consumers' search behavior.

Optimal price with a hidden fee

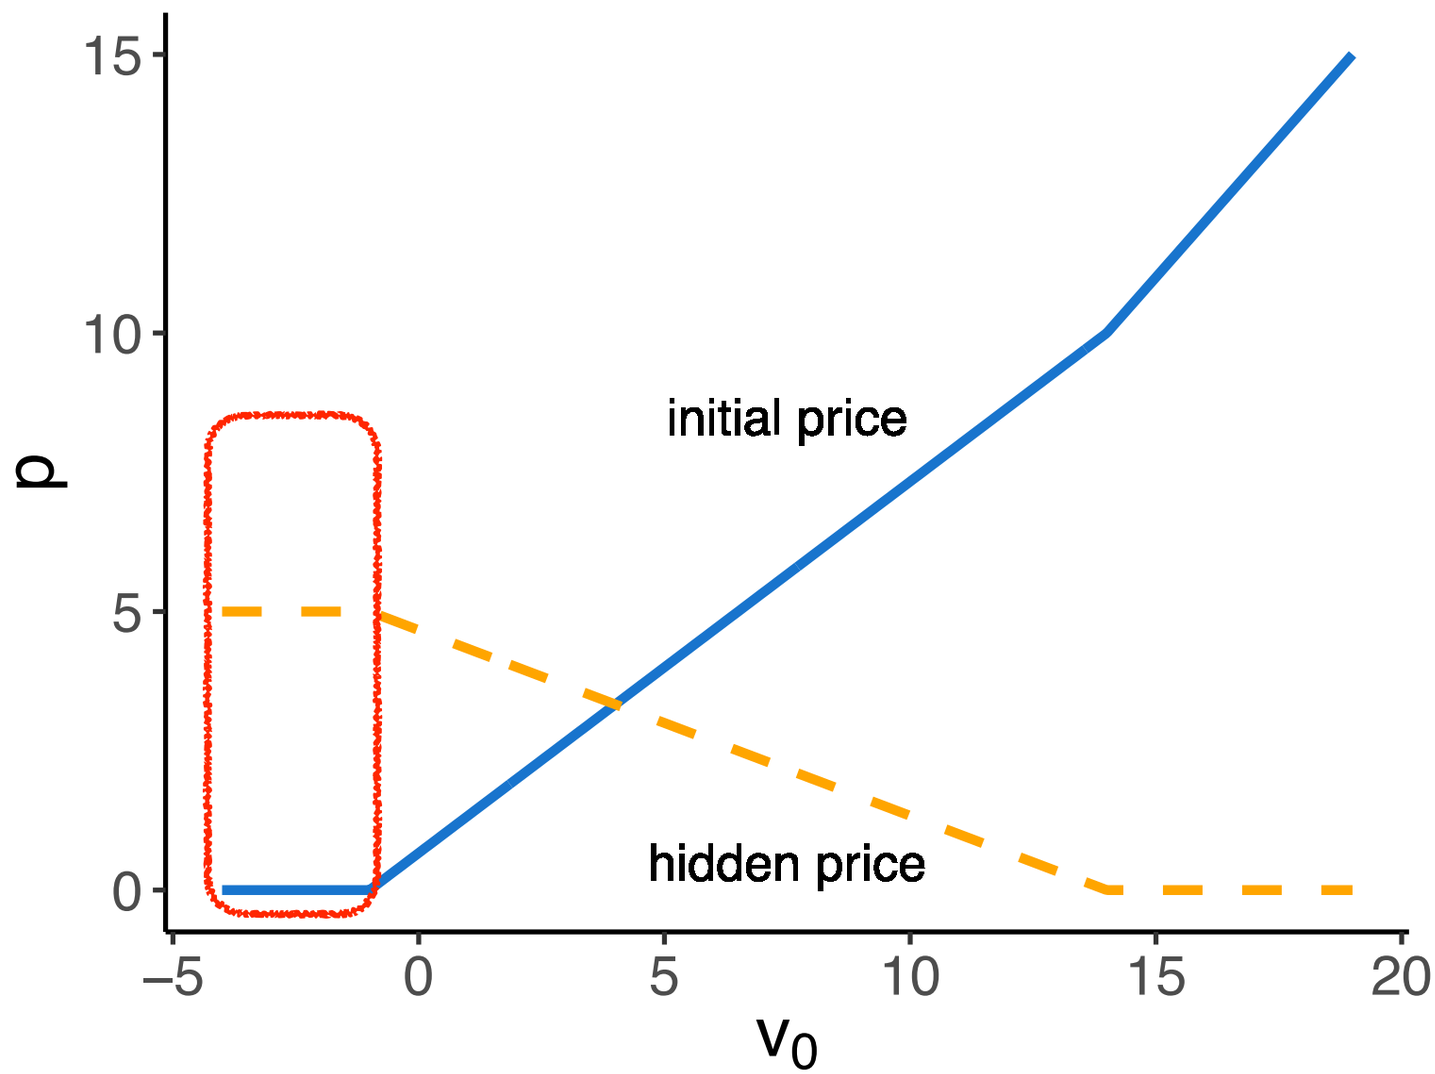
Proposition 2. *If* $\max\{-m/2, -3\sigma^2/4c + m\} < v_0 < 3\sigma^2/4c + m$*, then the optimal initial price is* $p_1^* = 2v_0/3 + m/3$ *and the optimal hidden fee is* $\Delta p^* = \sigma^2/4c + (m - v_0)/3$*. The optimal total price is* $p_1^* + \Delta p^* = v_0/3 + \sigma^2/4c + 2m/3$*, which is strictly higher than the optimal price without a hidden fee,* p_{wo}^**.*

If $-\sigma^2/4c < v_0 \leq -m/2$*, then the optimal initial price is* $p_1^* = 0$ *and the optimal hidden fee is* $\Delta p^* = \sigma^2/4c + m/2$*.*

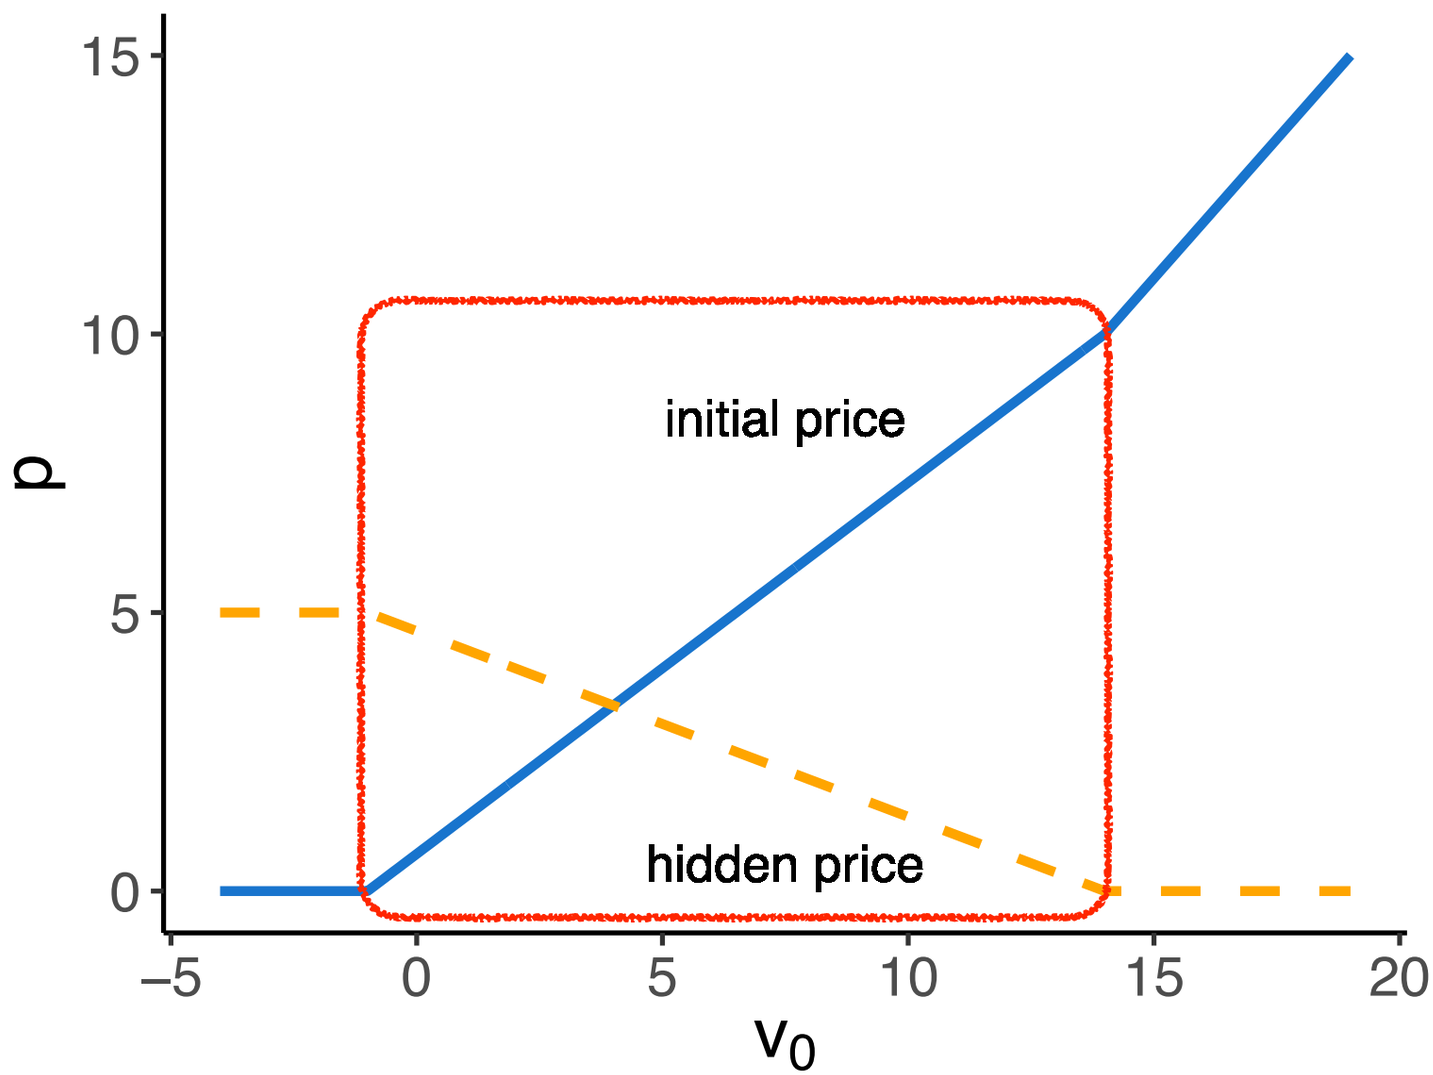
Optimal Price with a hidden fee



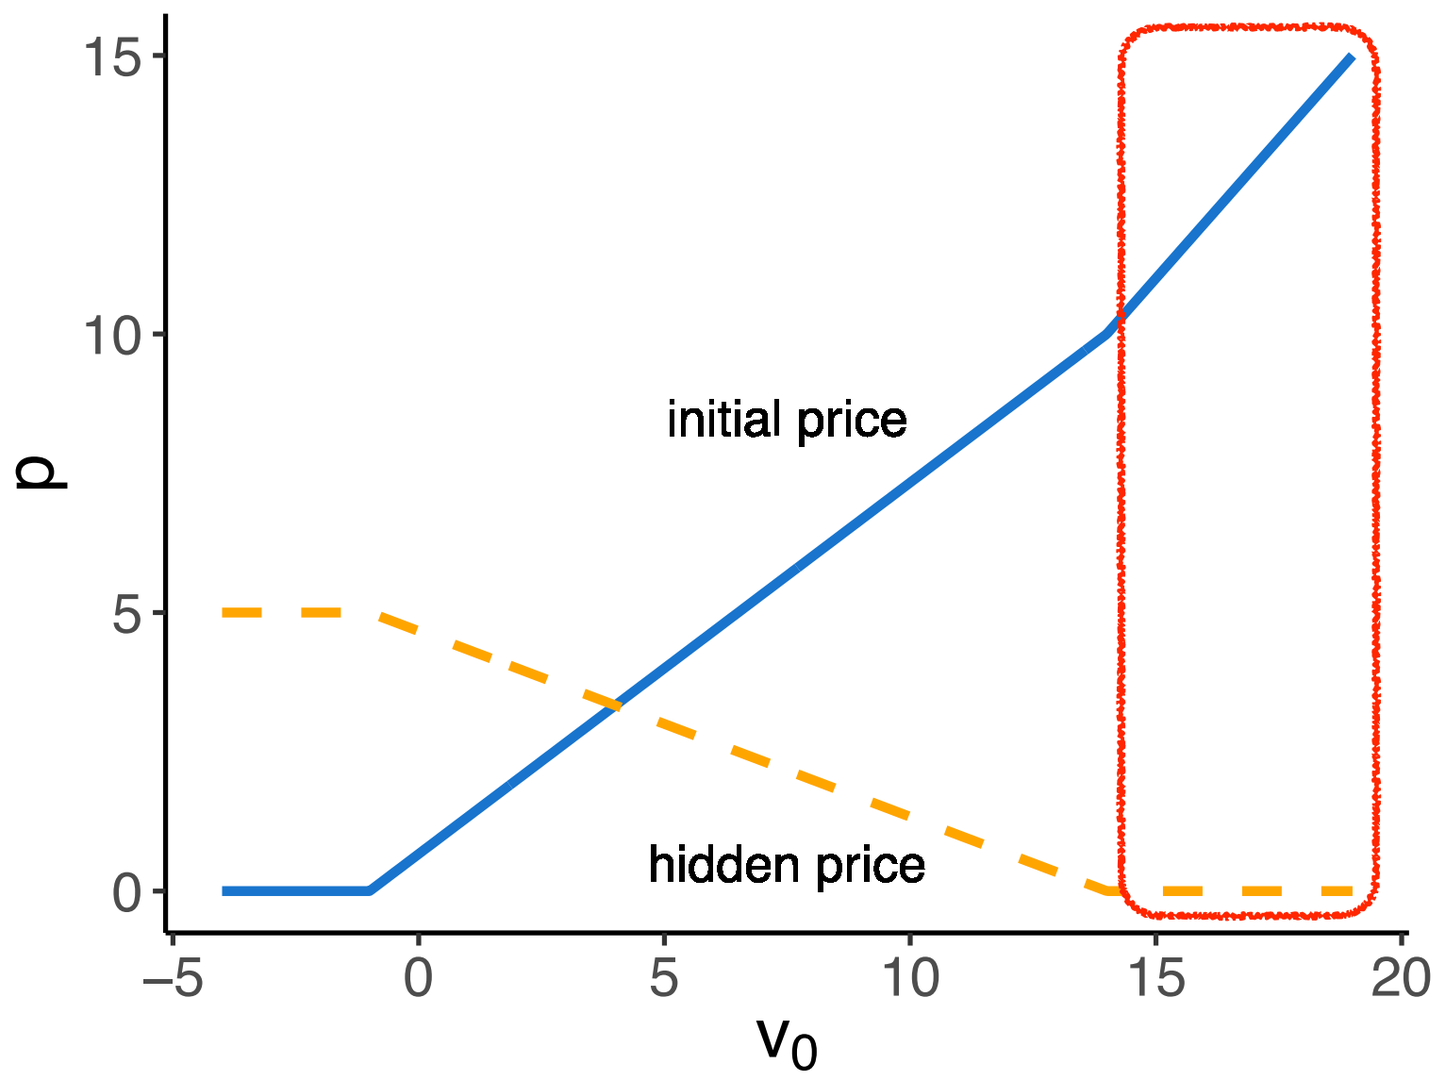
Optimal Price with a hidden fee



Optimal Price with a hidden fee



Optimal Price with a hidden fee



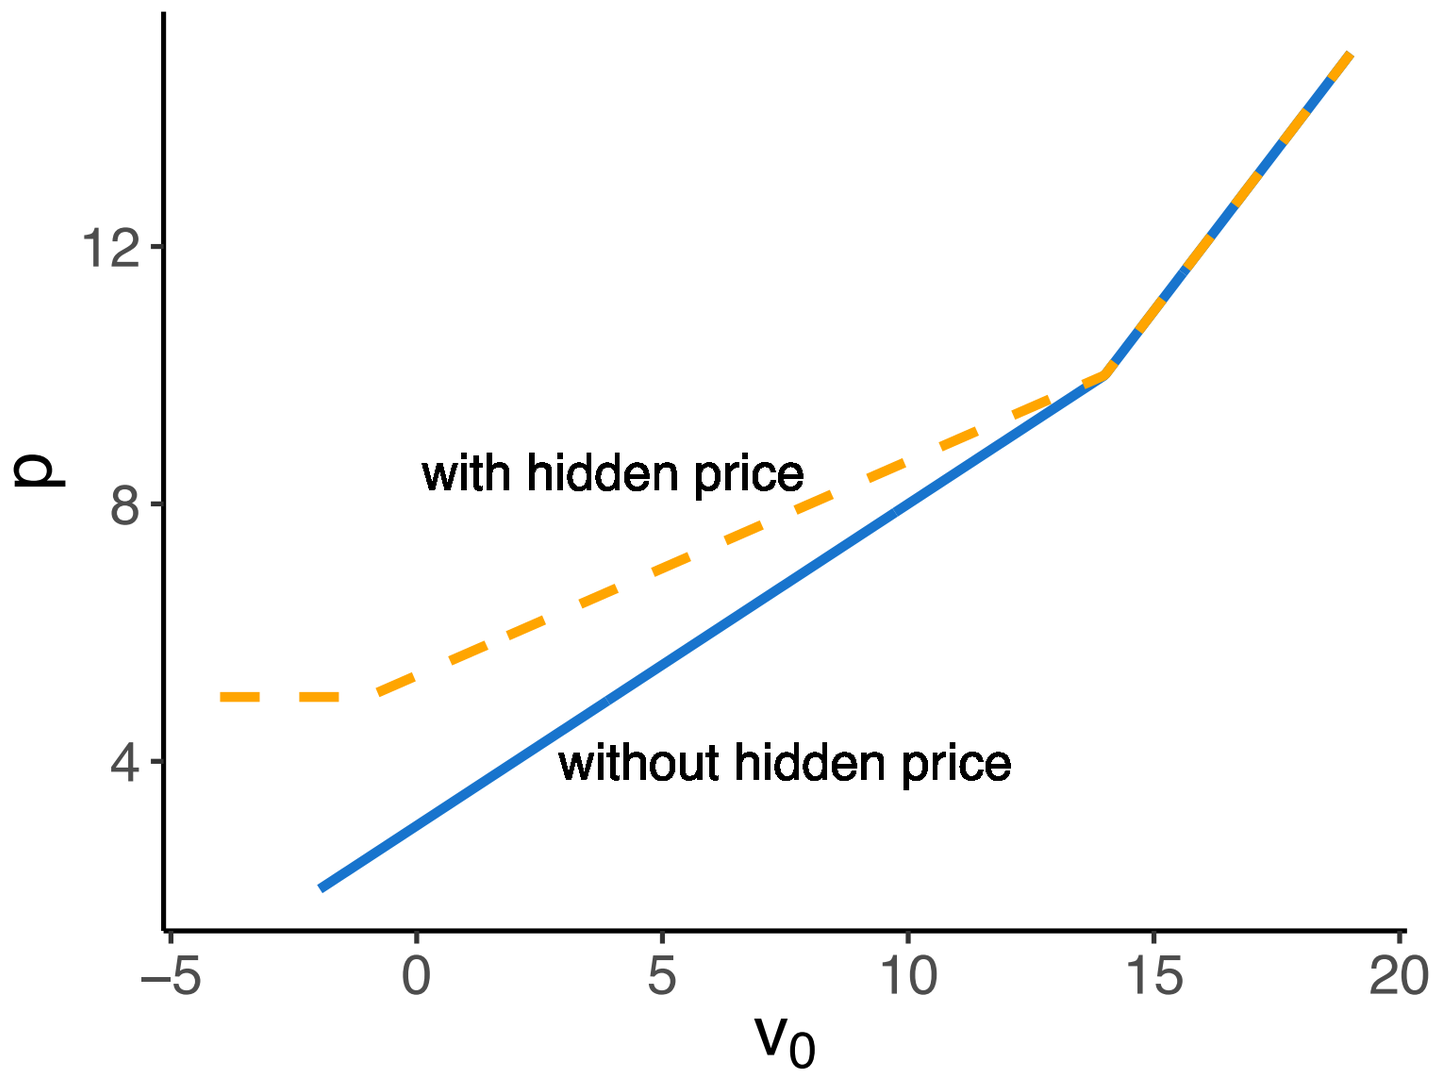
Comparative statics of the optimal price with hidden fee

- The hidden fee Δp increases in the signal informativeness σ^2, the marginal cost m, and decreases in the search cost c, the initial valuation v_0

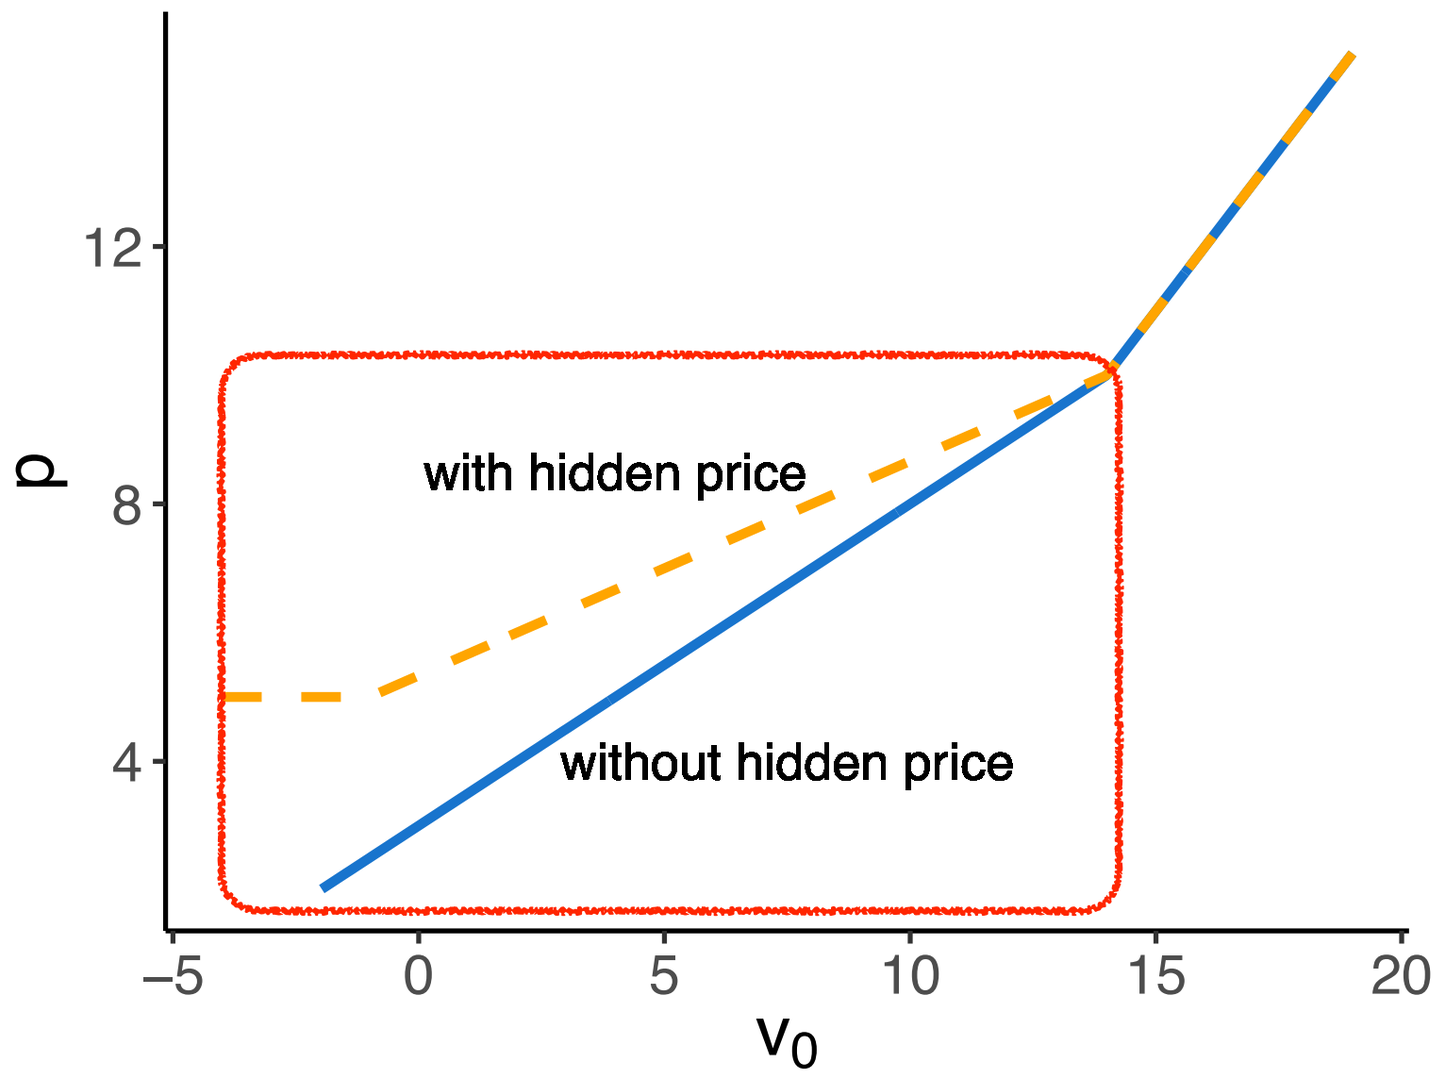
- The initial price p increases in v_0 and m (it does not depend on σ^2 and c)

- The total price $p + \Delta p$ increases in v_0, σ^2, m, and decreases in c

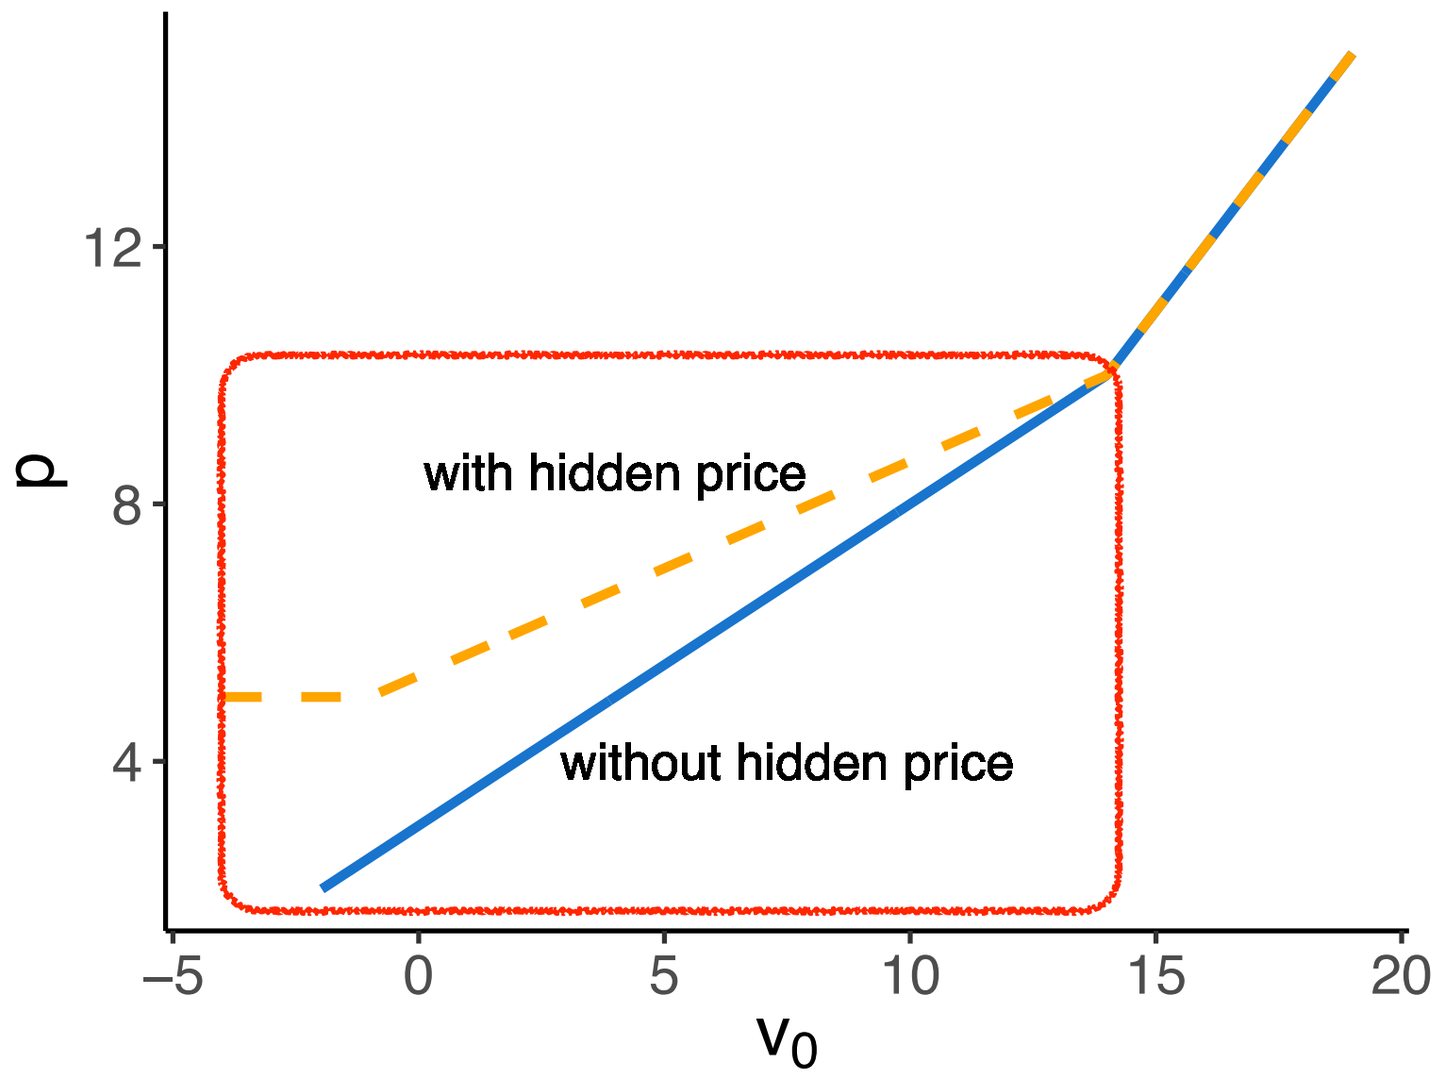
Optimal (total) price with and without a hidden fee



Strictly higher profit with a hidden fee (red area)



Strictly higher expected search time with a hidden fee (red area)



Heterogenous consumers

Heterogenous consumers

1. Heterogenous learning speeds

2. Heterogenous initial valuations

Heterogenous learning speeds

- Two groups of consumers with $\sigma \in \{\sigma^H, \sigma^L\}$, where $\sigma^H > \sigma^L$
- $Prob(\sigma = \sigma^H) = \rho_\sigma$
- Distribution of consumer types is common knowledge
- Realized type is each consumer’s private information
- Firm's pricing decision can lead to different strategic effects on different consumer segments
  - e.g., a higher price may generate higher profits among fast-learning consumers, but may drive slow-learning consumers out of the market

Total price with hidden fees may be lower than the price without hidden fees

- Sufficient condition:

$$\rho_\sigma < \widehat{\rho_\sigma},\ \sigma_H > \sqrt{5}\sigma_L,\ \max\{-m/2, -3\sigma_L^2/4c\} < v_0 < -\sigma_L^2/4c + m$$

- Key mechanism:

<u>Without hidden fees:</u>

Not profitable to sell to slow-learning consumers

Sellers set the price optimal for fast-learning consumers (high price)

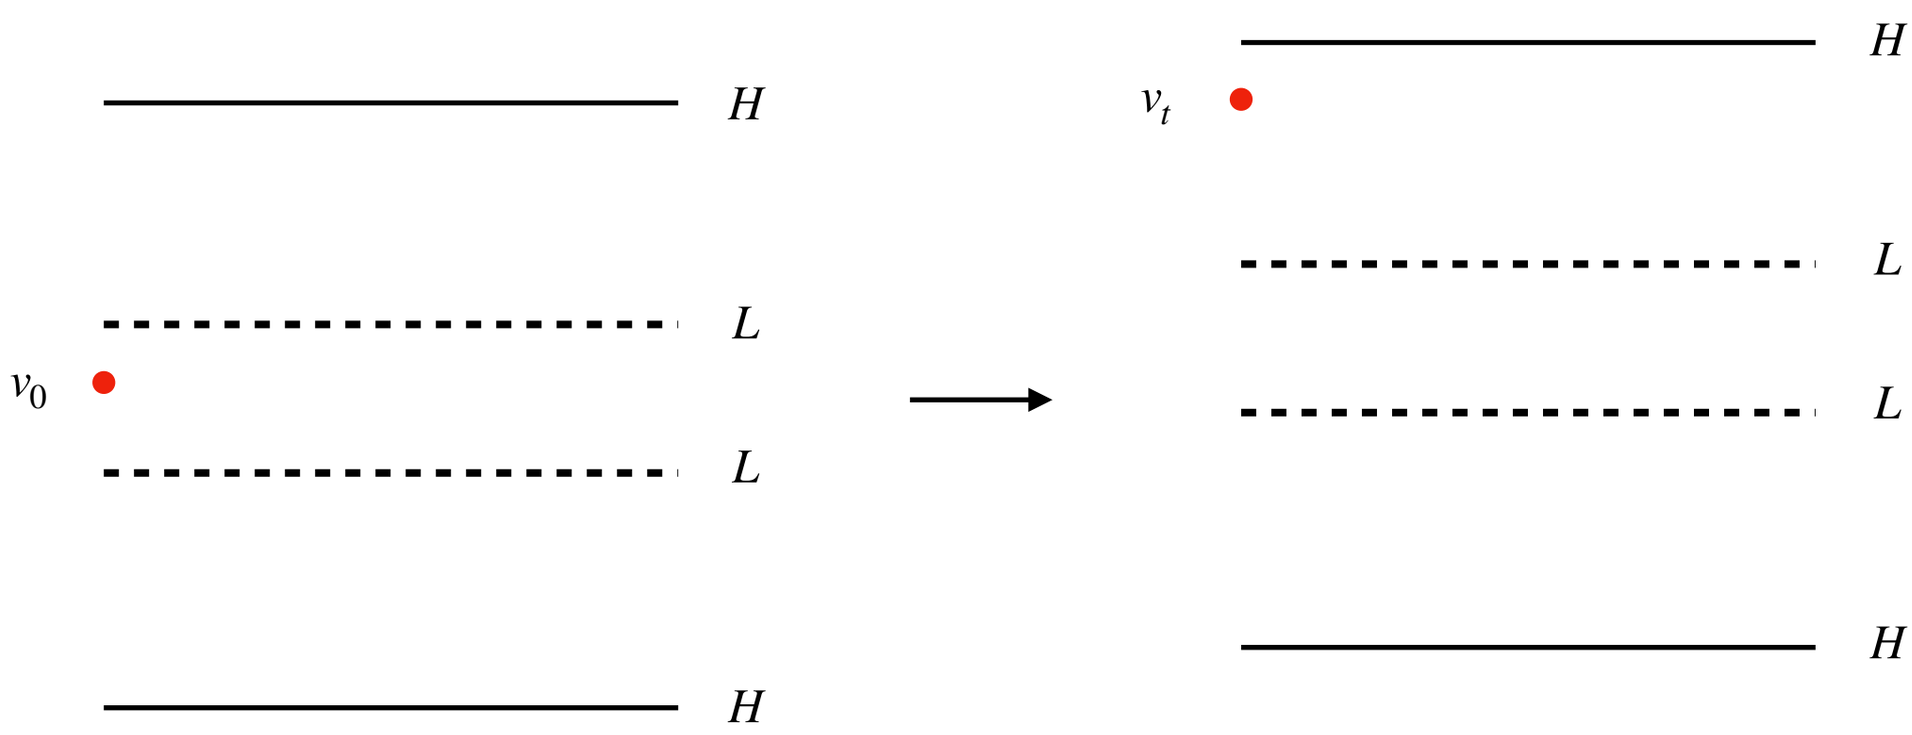
<u>With hidden fees:</u>

profitable to sell to both types of consumers

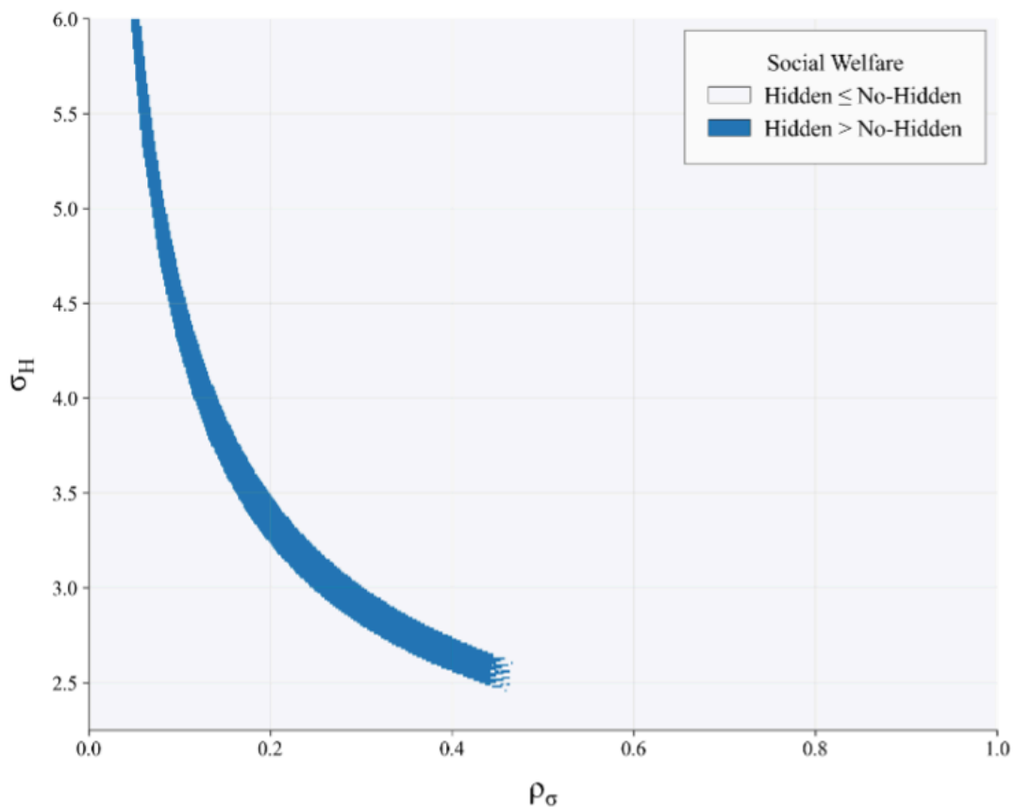
reduce the price to expand the market (low price)

Expected search time

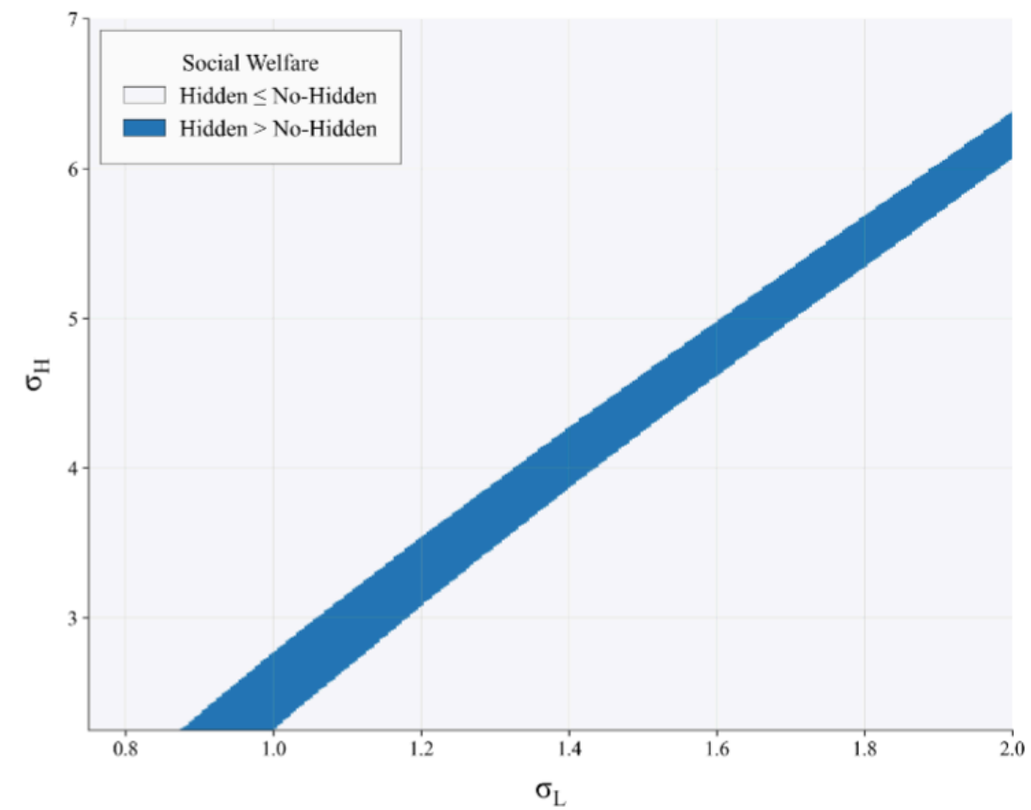
- Consumer search behavior exhibits different patterns when compared with the homogeneous consumer case
- Homogeneous case: $\mathbf{E}(\tau_1) \leq \mathbf{E}(\tau_2)$
- This case: $\mathbf{E}(\tau_1^H) > \mathbf{E}(\tau_2^H)$



The use of hidden fee can even increase social welfare



(a)



(b)

Heterogenous initial valuations

- Two groups of consumers with $v_0 \in \{v_0^H, v_0^L\}$, where $v_0^H > v_0^L$
- $Prob(v_0 = v_0^H) = \rho_v$
- Distribution of consumer types is common knowledge
- Realized type is each consumer's private information

Total price with hidden fees may be lower than the price without hidden fees

- Sufficient condition:

(1)$\rho_v < \widehat{\rho_v}$, $v_0^H - v_0^L > \sigma^2/c$, and
$\max\{-m/2, -3\sigma^2/4c + m\} < v_0^L < -\sigma^2/4c + m < v_0^H < 3\sigma^2/4c + m$

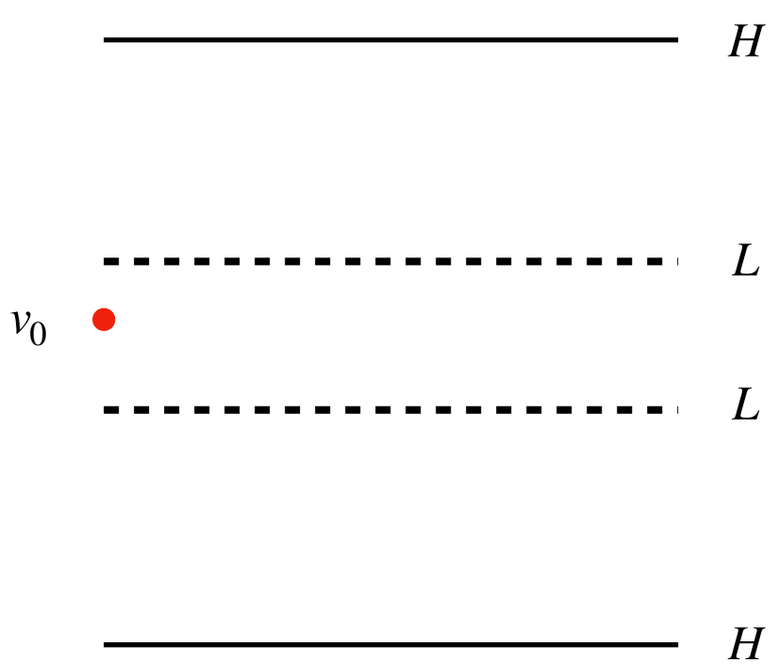
or

(2) $\rho_v < \widehat{\rho_v}'$, $v_0^H - v_0^L > \sigma^2/c$,
$-\sigma^2/4c < v_0^L < -\sigma^2/4c + m < v_0^H < 3\sigma^2/4c + m$, $v_0^L < -m/2$, and
$m < \sigma^2/2c$.

Expected search time

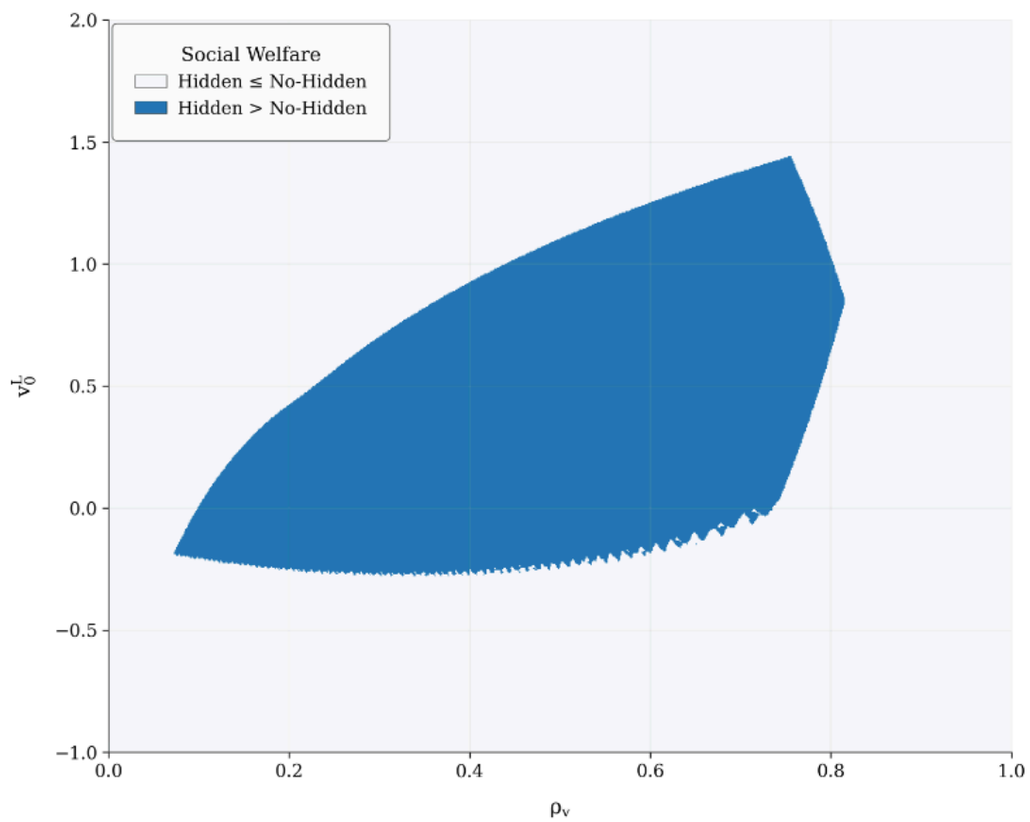
- Consumer search behavior qualitatively differ from the heterogeneous learning speeds case
- This case: $\mathbf{E}(\tau_1^H) = \mathbf{E}(\tau_2^H) = 0$

heterogeneous learning speeds

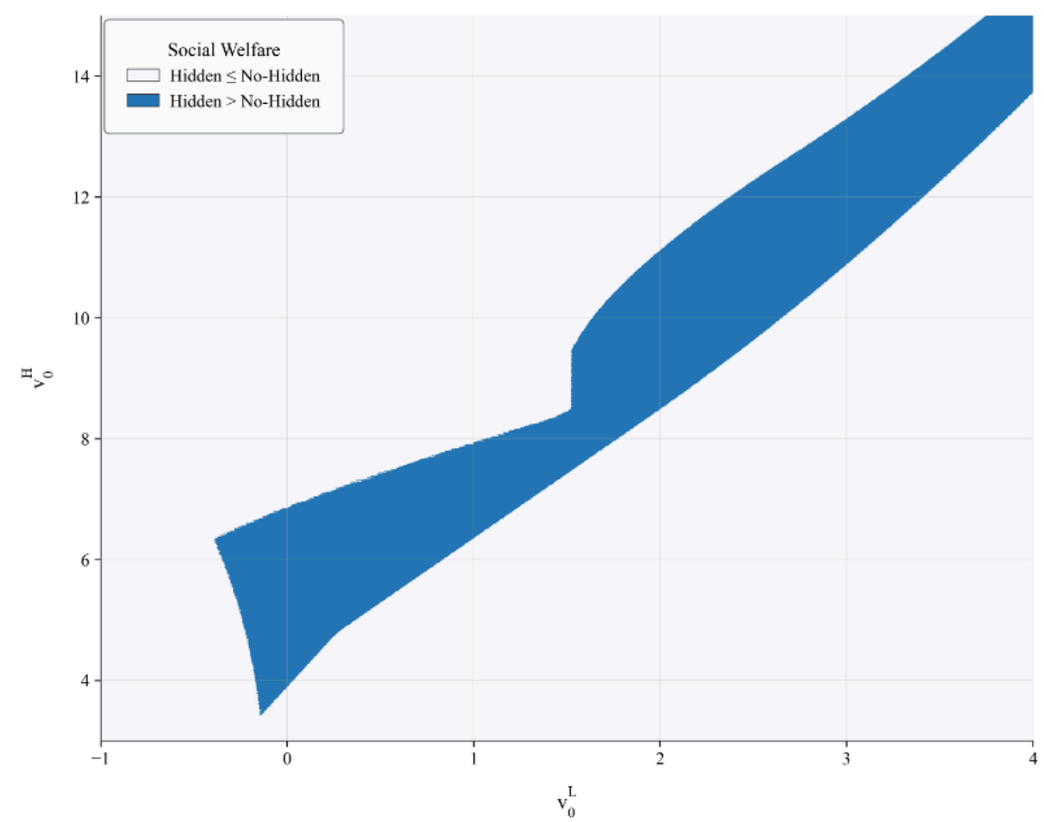


heterogeneous initial valuations

The use of hidden fee can even increase social welfare



(a)



(b)

Policy implications

Nuance Over Blanket Bans

- Hidden fees can expand market coverage and lower the price

⇒ May improve social welfare

- No one-size-fits-all approach for regulating the use of it
- Banning hidden fees in highly heterogeneous markets could backfire: can shut vulnerable consumers out of the market
- Regulators should analyze the composition of the customer base, particularly the degree of consumer heterogeneity

Extension

Some consumers are aware of the hidden fee

- ρ proportion of the consumers are unaware of the possibility of hidden fees

- Remaining $1 - \rho$ proportion of the consumers are aware of it
  $\Rightarrow$ rationally anticipate the seller's pricing strategies in the second stage

- <u>Proposition:</u> For any $\rho > 0$, there exist parameters such that the firm's expected profit is strictly higher with a hidden fee.

Thanks!
